1 GENERAL DESCRIPTION

The NuMicro[™] NUC100 Series 32-bit microcontroller is embedded with ARM[®] Cortex[™]-M0 core for industrial control and applications that need rich communication interfaces. The Cortex[™]-M0 is the newest ARM[®] embedded processor with 32-bit performance and at a cost equivalent to traditional 8-bit microcontroller. The NuMicro[™] NUC100 Series includes NUC100, NUC120, NUC130 and NUC140 product lines.

The NuMicro[™] NUC130 Automotive Line with CAN function is embedded with Cortex[™]-M0 core running up to 50 MHz with 32K/64K/128K bytes embedded flash, 4K/8K/16K bytes embedded SRAM, and 4 Kbytes loader ROM for the ISP. The NUC130 is also equipped with plenty of peripheral devices, such as Timers, Watchdog Timer, RTC, PDMA, UART, SPI, I²C, I²S, PWM Timer, GPIO, LIN, CAN, PS/2, 12-bit ADC, Analog Comparator, Low Voltage Reset Controller and Brown-out Detector.

The NuMicro[™] NUC140 Connectivity Line with USB 2.0 full-speed and CAN functions is embedded with Cortex[™]-M0 core running up to 50 MHz with 32K/64K/128K bytes embedded flash, 4K/8K/16K bytes embedded SRAM, and 4 Kbytes loader ROM for the ISP. The NUC140 is also equipped with plenty of peripheral devices, such as Timers, Watchdog Timer, RTC, PDMA, UART, SPI, I²C, I²S, PWM Timer, GPIO, LIN, CAN, PS/2, USB 2.0 FS Device, 12-bit ADC, Analog Comparator, Low Voltage Reset Controller and Brown-out Detector.

Table 1-1 Connectivity Support Table

2 FEATURES

The equipped features are dependent on the product line and their sub products.

2.1 NuMicro™ NUC130 Features – Automotive Line

- Core
 - ARM[®] Cortex[™]-M0 core running up to 50 MHz
 - One 24-bit system timer
 - Supports low power sleep mode
 - Single-cycle 32-bit hardware multiplier
 - NVIC for the 32 interrupt inputs, each with 4-levels of priority
 - Serial Wire Debug supports with 2 watchpoints/4 breakpoints
- Build-in LDO for wide operating voltage ranges from 2.5 V to 5.5 V
- Flash Memory
 - 32K/64K/128K bytes Flash for program code
 - 4KB flash for ISP loader
 - Supports In-system program (ISP) application code update
 - 512 byte page erase for flash
 - Configurable data flash address and size for 128KB system, fixed 4KB data flash for the 32KB and 64KB system
 - Supports 2 wire ICP update through SWD/ICE interface
 - Supports fast parallel programming mode by external programmer
- SRAM Memory
 - 4K/8K/16K bytes embedded SRAM
 - Supports PDMA mode
- PDMA (Peripheral DMA)
 - Supports 9 channels PDMA for automatic data transfer between SRAM and peripherals
- Clock Control
 - Flexible selection for different applications
 - Built-in 22.1184 MHz high speed OSC for system operation
 - Trimmed to \pm 1 % at +25 °C and V_{DD} = 5 V
 - Trimmed to \pm 3 % at -40 °C ~ +85 °C and V_{DD} = 2.5 V ~ 5.5 V
 - Built-in 10 kHz low speed OSC for Watchdog Timer and Wake-up operation
 - Supports one PLL, up to 50 MHz, for high performance system operation External 4~24 MHz high speed crystal input for precise timing operation
 - External 32.768 kHz low speed crystal input for RTC function and low power system operation
- GPIO
 - Four I/O modes:
 - Quasi bi-direction
 - Push-Pull output
 - Open-Drain output
 - Input only with high impendence
 - TTL/Schmitt trigger input selectable
 - I/O pin configured as interrupt source with edge/level setting
 - Supports High Driver and High Sink I/O mode
- Timer

nuvoton

- Supports 4 sets of 32-bit timers with 24-bit up-timer and one 8-bit pre-scale counter
- Independent clock source for each timer
- Provides one-shot, periodic, toggle and continuous counting operation modes
- Support event counting function
- Support input capture function
- Watchdog Timer
 - Multiple clock sources
 - 8 selectable time out period from 1.6ms ~ 26.0sec (depending on clock source)
 - Wake-up from Power-down or Idle mode
 - Interrupt or reset selectable on watchdog time-out
- RTC
 - Supports software compensation by setting frequency compensate register (FCR)
 - Supports RTC counter (second, minute, hour) and calendar counter (day, month, year)
 - Supports Alarm registers (second, minute, hour, day, month, year)
 - Selectable 12-hour or 24-hour mode
 - Automatic leap year recognition
 - Supports periodic time tick interrupt with 8 period options 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2 and 1 second
 - Supports wake-up function
- PWM/Capture
 - Up to four built-in 16-bit PWM generators providing eight PWM outputs or four complementary paired PWM outputs
 - Each PWM generator equipped with one clock source selector, one clock divider, one
 8-bit prescaler and one Dead-Zone generator for complementary paired PWM
 - Up to eight 16-bit digital Capture timers (shared with PWM timers) provide eight rising/falling capture inputs
 - Supports Capture interrupt
- UART
 - Up to three UART controllers
 - UART ports with flow control (TXD, RXD, CTS and RTS)
 - UART0 with 64-byte FIFO is for high speed
 - UART1/2(optional) with 16-byte FIFO for standard device
 - Supports IrDA (SIR) and LIN function
 - Supports RS-485 9-bit mode and direction control.
 - Programmable baud-rate generator up to 1/16 system clock
 - Supports PDMA mode

SPI

- Up to four sets of SPI controller
- Supports SPI master/Slave mode
- Full duplex synchronous serial data transfer
- Variable length of transfer data from 8 to 32 bits
- MSB or LSB first data transfer
- Rx and Tx on both rising or falling edge of serial clock independently
- Two slave/device select lines when it is used as the master, and 1 slave/device select line when it is used as the slave
- Supports byte suspend mode in 32-bit transmission
- Supports PDMA mode
- Supports three wire, no slave select signal, bi-direction interface

- I²C
 - Up to two sets of I²C device
 - Master/Slave mode
 - Bidirectional data transfer between masters and slaves
 - Multi-master bus (no central master)
 - Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
 - Serial clock synchronization allows devices with different bit rates to communicate via one serial bus
 - Serial clock synchronization used as a handshake mechanism to suspend and resume serial transfer
 - Programmable clocks allow versatile rate control
 - Supports multiple address recognition (four slave address with mask option)
- |²S
 - Interface with external audio CODEC
 - Operated as either Master or Slave mode
 - Capable of handling 8-, 16-, 24- and 32-bit word sizes
 - Mono and stereo audio data supported
 - I²S and MSB justified data format supported
 - Two 8 word FIFO data buffers are provided, one for transmit and one for receive
 - Generates interrupt requests when buffer levels cross a programmable boundary
 - Supports two DMA requests, one for transmit and one for receive
- PS/2 Device Controller
 - Host communication inhibit and request to send detection
 - Reception frame error detection
 - Programmable 1 to 16 bytes transmit buffer to reduce CPU intervention
 - Double buffer for data reception
 - S/W override bus
- CAN 2.0
 - Supports CAN protocol version 2.0 part A and B
 - Bit rates up to 1M bit/s
 - 32 Message Objects
 - Each Message Object has its won identifier mask
 - Programmable FIFO mode (concatenation of Message Object)
 - Maskable interrupt
 - Disabled Automatic Re-transmission mode for Time Triggered CAN applications
 - Supports Power-down wake-up function
- EBI (External bus interface) support (100-pin and 64-pin Package Only)
 - Accessible space: 64KB in 8-bit mode or 128KB in 16-bit mode
 - Supports 8-/16-bit data width
 - Supports byte write in 16-bit data width mode
- ADC
 - 12-bit SAR ADC with 700K SPS
 - Up to 8-ch single-end input or 4-ch differential input
 - Single scan/single cycle scan/continuous scan
 - Each channel with individual result register
 - Scan on enabled channels
 - Threshold voltage detection
 - Conversion start by software programming or external input
 - Supports PDMA mode

- Analog Comparator
 - Up to two analog comparator
 - External input or internal band-gap voltage selectable at negative node
 - Interrupt when compare result change
 - Power-down wake-up
- One built-in temperature sensor with 1°C resolution
- Brown-out detector
 - With 4 levels: 4.5 V/3.8 V/2.7 V/2.2 V
 - Supports Brown-out Interrupt and Reset option
- Low Voltage Reset
 - Threshold voltage levels: 2.0 V
- Operating Temperature: -40°C~85°C
- Packages:
 - All Green package (RoHS)
 - LQFP 100-pin / 64-pin / 48-pin

2.2 NuMicro[™] NUC140 Features – Connectivity Line

- Core
 - ARM[®] Cortex[™]-M0 core runs up to 50 MHz
 - One 24-bit system timer
 - Supports low power sleep mode
 - Single-cycle 32-bit hardware multiplier
 - NVIC for the 32 interrupt inputs, each with 4-levels of priority
 - Serial Wire Debug supports with 2 watchpoints/4 breakpoints
- Build-in LDO for wide operating voltage ranges from 2.5 V to 5.5 V
- Flash Memory
 - 32K/64K/128K bytes Flash for program code
 - 4KB flash for ISP loader
 - Support In-system program (ISP) application code update
 - 512 byte page erase for flash
 - Configurable data flash address and size for 128KB system, fixed 4KB data flash for the 32KB and 64KB system
 - Support 2 wire ICP update through SWD/ICE interface
 - Support fast parallel programming mode by external programmer
- SRAM Memory
 - 4K/8K/16K bytes embedded SRAM
 - Support PDMA mode
- PDMA (Peripheral DMA)
 - Support 9 channels PDMA for automatic data transfer between SRAM and peripherals
- Clock Control
 - Flexible selection for different applications
 - Built-in 22.1184 MHz high speed OSC for system operation
 - Trimmed to \pm 1 % at +25 °C and V_{DD} = 5 V
 - Trimmed to \pm 3 % at -40 °C ~ +85 °C and V_{DD} = 2.5 V ~ 5.5 V
 - Built-in 10 kHz low speed OSC for Watchdog Timer and Wake-up operation
 - Support one PLL, up to 50 MHz, for high performance system operation
 - External 4~24 MHz high speed crystal input for USB and precise timing operation
 - External 32.768 kHz low speed crystal input for RTC function and low power system operation
- GPIO
 - Four I/O modes:
 - Quasi bi-direction
 - Push-Pull output
 - Open-Drain output
 - Input only with high impendence
 - TTL/Schmitt trigger input selectable
 - I/O pin configured as interrupt source with edge/level setting
 - Supports High Driver and High Sink I/O mode
- Timer
 - Supports 4 sets of 32-bit timers with 24-bit up-timer and one 8-bit pre-scale counter
 - Independent clock source for each timer

- Provides one-shot, periodic, toggle and continuous counting operation modes
- Supports event counting function
 - Supports input capture function
- Watchdog Timer
 - Multiple clock sources
 - 8 selectable time out period from 1.6ms ~ 26.0sec (depending on clock source)
 - Wake-up from Power-down or Idle mode
 - Interrupt or reset selectable on watchdog time-out
- RTC
 - Support software compensation by setting frequency compensate register (FCR)
 - Support RTC counter (second, minute, hour) and calendar counter (day, month, year)
 - Support Alarm registers (second, minute, hour, day, month, year)
 - Selectable 12-hour or 24-hour mode
 - Automatic leap year recognition
 - Support periodic time tick interrupt with 8 period options 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2 and 1 second
 - Support wake-up function
- PWM/Capture
 - Built-in up to four 16-bit PWM generators provide eight PWM outputs or four complementary paired PWM outputs
 - Each PWM generator equipped with one clock source selector, one clock divider, one
 8-bit prescaler and one Dead-Zone generator for complementary paired PWM
 - Up to eight 16-bit digital Capture timers (shared with PWM timers) provide eight rising/falling capture inputs
 - Support Capture interrupt
- UART
 - Up to three UART controllers
 - UART ports with flow control (TXD, RXD, CTS and RTS)
 - UART0 with 64-byte FIFO is for high speed
 - UART1/2(optional) with 16-byte FIFO for standard device
 - Support IrDA (SIR) and LIN function
 - Support RS-485 9-bit mode and direction control.
 - Programmable baud-rate generator up to 1/16 system clock
 - Support PDMA mode

SPI

- Up to four sets of SPI controller
- Supports SPI master/Slave mode
- Full duplex synchronous serial data transfer
- Variable length of transfer data from 8 to 32 bits
- MSB or LSB first data transfer
- Rx and Tx on both rising or falling edge of serial clock independently
- 2 slave/device select lines when it is as the master, and 1 slave/device select line when it is as the slave
- Support byte suspend mode in 32-bit transmission
- Support PDMA mode
- Support three wire, no slave select signal, bi-direction interface

- I²C
 - Up to two sets of I²C device
 - Master/Slave mode
 - Bidirectional data transfer between masters and slaves
 - Multi-master bus (no central master)
 - Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
 - Serial clock synchronization allows devices with different bit rates to communicate via one serial bus
 - Serial clock synchronization used as a handshake mechanism to suspend and resume serial transfer
 - Programmable clocks allow versatile rate control
 - Support multiple address recognition (four slave addresses with mask option)
- |²S
 - Interface with external audio CODEC
 - Operated as either Master or Slave mode
 - Capable of handling 8-, 16-, 24- and 32-bit word sizes
 - Mono and stereo audio data supported
 - I²S and MSB justified data format supported
 - Two 8 word FIFO data buffers are provided, one for transmit and one for receive
 - Generates interrupt requests when buffer levels cross a programmable boundary
 - Support two DMA requests, one for transmit and one for receive
- CAN 2.0
 - Supports CAN protocol version 2.0 part A and B
 - Bit rates up to 1M bit/s
 - 32 Message Objects
 - Each Message Object has its won identifier mask
 - Programmable FIFO mode (concatenation of Message Object)
 - Maskable interrupt
 - Disabled Automatic Re-transmission mode for Time Triggered CAN applications
 - Support power down wake-up function
- PS/2 Device Controller
 - Host communication inhibit and request to send detection
 - Reception frame error detection
 - Programmable 1 to 16 bytes transmit buffer to reduce CPU intervention
 - Double buffer for data reception
 - S/W override bus
- USB 2.0 Full-Speed Device
 - One set of USB 2.0 FS Device 12Mbps
 - On-chip USB Transceiver
 - Provide 1 interrupt source with 4 interrupt events
 - Support Control, Bulk In/Out, Interrupt and Isochronous transfers
 - Auto suspend function when no bus signaling for 3 ms
 - Provide 6 programmable endpoints
 - Include 512 Bytes internal SRAM as USB buffer
 - Provide remote wake-up capability
- EBI (External bus interface) support (100-pin and 64-pin Package Only)
 - Accessible space: 64KB in 8-bit mode or 128KB in 16-bit mode
 - Support 8-/16-bit data width
 - Support byte write in 16-bit data width mode

- ADC
 - 12-bit SAR ADC with 700K SPS
 - Up to 8-ch single-end input or 4-ch differential input
 - Single scan/single cycle scan/continuous scan
 - Each channel with individual result register
 - Scan on enabled channels
 - Threshold voltage detection
 - Conversion start by software programming or external input
 - Support PDMA Mode
- Analog Comparator
 - Up to two analog comparators
 - External input or internal band-gap voltage selectable at negative node
 - Interrupt when compare result change
 - Power down wake-up
- One built-in temperature sensor with 1°C resolution
- Brown-out detector
 - With 4 levels: 4.5 V/3.8 V/2.7 V/2.2 V
 - Support Brown-out Interrupt and Reset option
- Low Voltage Reset
 - Threshold voltage levels: 2.0 V
- Operating Temperature: -40°C~85°C
- Packages:
 - All Green package (RoHS)
 - LQFP 100-pin / 64-pin / 48-pin

5 FUNCTIONAL DESCRIPTION

5.1 ARM[®] Cortex[™]-M0 Core

The Cortex[™]-M0 processor is a configurable, multistage, 32-bit RISC processor. It has an AMBA AHB-Lite interface and includes an NVIC component. It also has optional hardware debug functionality. The processor can execute Thumb code and is compatible with other Cortex-M profile processor. The profile supports two modes -Thread mode and Handler mode. Handler mode is entered as a result of an exception. An exception return can only be issued in Handler mode. Thread mode is entered on Reset, and can be entered as a result of an exception return. Figure 5-1 shows the functional controller of processor.

Figure 5-1 Functional Controller Diagram

The implemented device provides the following features:

- A low gate count processor:
 - ♦ ARMv6-M Thumb® instruction set
 - Thumb-2 technology
 - ARMv6-M compliant 24-bit SysTick timer
 - A 32-bit hardware multiplier
 - Supports little-endian data accesses
 - Capable of having deterministic, fixed-latency, interrupt handling
 - Load/store-multiples and multicycle-multiplies that can be abandoned and restarted to facilitate rapid interrupt handling
 - C Application Binary Interface compliant exception model. This is the ARMv6-M, C Application Binary Interface (C-ABI) compliant exception model that enables the use of pure C functions as interrupt handlers
 - Low power sleep mode entry using Wait For Interrupt (WFI), Wait For Event

(WFE) instructions, or the return from interrupt sleep-on-exit feature

- NVIC:
 - ♦ 32 external interrupt inputs, each with four levels of priority
 - Dedicated Non-Maskable Interrupt (NMI) input.
 - Supported for both level-sensitive and pulse-sensitive interrupt lines
 - Wake-up Interrupt Controller (WIC), providing ultra-low power sleep mode support
- Debug support:
 - Four hardware breakpoints
 - Two watchpoints
 - Program Counter Sampling Register (PCSR) for non-intrusive code profiling
 - Single step and vector catch capabilities
- Bus interfaces:
 - Single 32-bit AMBA-3 AHB-Lite system interface that provides simple integration to all system peripherals and memory
 - Single 32-bit slave port that supports DAP (Debug Access Port)

5.2 System Manager

5.2.1 Overview

This chapter includes the following sections:

- System Resets
- System Memory Map
- System management registers for Part Number ID, chip reset and on-chip controllers reset, multi-functional pin control
- System Timer (SysTick)
- Nested Vectored Interrupt Controller (NVIC)
- System Control registers

5.2.2 System Reset

The system reset can be issued by one of the below listed events. For these reset event flags can be read by RSTSRC register.

- Power-on Reset
- Low level on the /RESET pin
- Watchdog Time Out Reset
- Low Voltage Reset
- Brown-out Detector Reset
- CPU Reset
- System Reset

System Reset and Power-On Reset all reset the whole chip including all peripherals. The difference between System Reset and Power-On Reset is external crystal circuit and ISPCON.BS bit. System Reset does not reset external crystal circuit and ISPCON.BS bit, but Power-On Reset does.

5.2.3 System Power Distribution

In this chip, the power distribution is divided into three segments.

- Analog power from AV_{DD} and AV_{SS} provides the power for analog components operation.
- Digital power from V_{DD} and V_{SS} supplies the power to the internal regulator which provides a fixed 2.5 V power for digital operation and I/O pins.
- USB transceiver power from V_{BUS} offers the power for operating the USB transceiver. (For NuMicro™ NUC140 only)

The outputs of internal voltage regulators, LDO and V_{DD33} , require an external capacitor which should be located close to the corresponding pin. Analog power (AV_{DD}) should be the same voltage level of the digital power (V_{DD}). Figure 5-2 shows the power distribution of NuMicroTM NUC140 and Figure 5-3 shows the power distribution of NuMicroTM NUC130.

Figure 5-2 NuMicro™ NUC140 Power Distribution Diagram

nuvoTon

Figure 5-3 NuMicro™ NUC130 Power Distribution Diagram

5.2.4 System Memory Map

The NuMicro[™] NUC100 Series provides 4G-byte addressing space. The memory locations assigned to each on-chip controllers are shown in the following table. The detailed register definition, memory space, and programming detailed will be described in the following sections for each on-chip peripherals. The NuMicro[™] NUC100 Series only supports little-endian data format.

Address Space	Token	Controllers
Flash and SRAM Memory Spa	ce	100 CM
0x0000_0000 – 0x0001_FFFF	FLASH_BA	FLASH Memory Space (128KB)
0x2000_0000 – 0x2000_3FFF	SRAM_BA	SRAM Memory Space (16KB)
0x6000_0000 – 0x6001_FFFF	EXTMEM_BA	External Memory Space (128KB)
AHB Controllers Space (0x500	00_0000 – 0x50	1F_FFFF)
0x5000_0000 – 0x5000_01FF	GCR_BA	System Global Control Registers
0x5000_0200 – 0x5000_02FF	CLK_BA	Clock Control Registers
0x5000_0300 – 0x5000_03FF	INT_BA	Interrupt Multiplexer Control Registers
0x5000_4000 – 0x5000_7FFF	GPIO_BA	GPIO Control Registers
0x5000_8000 – 0x5000_BFFF	PDMA_BA	Peripheral DMA Control Registers

RSTS_CPU	Reserved	RSTS_SYS	RSTS_BOD	RSTS_LVR	RSTS_WDT	RSTS_RESE T	RSTS_POR		

Bits	Description	
[31:8]	Reserved	Reserved
		The RSTS_CPU flag is set by hardware if software writes CPU_RST (IPRSTC1[1]) 1 to reset Cortex-M0 CPU kernel and Flash memory controller (FMC).
[7]	RSTS_CPU	1 = The Cortex-M0 CPU kernel and FMC are reset by software setting CPU_RST to 1.
		0 = No reset from CPU
		Software can write 1 to clear this bit to 0.
[6]	Reserved	Reserved
		The RSTS_SYS flag is set by the "reset signal" from the Cortex_M0 kernel to indicate the previous reset source.
[5]	RSTS_SYS	1 = The Cortex_M0 had issued the reset signal to reset the system by software writin 1 to bit SYSRESETREQ(AIRCR[2], Application Interrupt and Reset Control Registe address = 0xE000ED0C) in system control registers of Cortex_M0 kernel.
V. S. A	5	0 = No reset from Cortex_M0
Nat	23	Software can write 1 to clear this bit to 0.
Ũ	200	The RSTS_BOD flag is set by the "reset signal" from the Brown-out-Detector to indicate the previous reset source.
[4]	RSTS_BOD	1 = The BOD had issued the reset signal to reset the system
	Non G	0 = No reset from BOD
	202	Software can write 1 to clear this bit to 0.
[3]	RSTS_LVR	The RSTS_LVR flag is set by the "reset signal" from the Low-Voltage-Reset controlle to indicate the previous reset source.
	<	1 = The LVR controller had issued the reset signal to reset the system.

		0 = No reset from LVR
		Software can write 1 to clear this bit to 0.
		The RSTS_WDT flag is set by the "reset signal" from the watchdog timer to indicate the previous reset source.
[2]	RSTS_WDT	1 = The watchdog timer had issued the reset signal to reset the system.
	_	0 = No reset from watchdog timer
		Software can write 1 to clear this bit to 0.
		The RSTS_RESET flag is set by the "reset signal" from the /RESET pin to indicate the previous reset source.
[1]	RSTS_RESET	1 = The Pin /RESET had issued the reset signal to reset the system.
		0 = No reset from /RESET pin
		Software can write 1 to clear this bit to 0.
		The RSTS_POR flag is set by the "reset signal" from the Power-On Reset (POR) controller or bit CHIP_RST (IPRSTC1[0]) to indicate the previous reset source.
[0]	RSTS_POR	1 = The Power-On Reset (POR) or CHIP_RST had issued the reset signal to reset the system.
		0 = No reset from POR or CHIP_RST
		Software can write 1 to clear this bit to 0.

7	6	5	4	3	2	1	0	
	Rese	erved		EBI_RST	PDMA_RST	CPU_RST	CHIP_RST	

 Bits	Description	
[31:4]	Reserved	Reserved
		EBI Controller Reset (write-protection bit in NUC130/NUC140 100-pin and 64-pin package)
		Set this bit to 1 will generate a reset signal to the EBI. User need to set this bit to 0 to release from the reset state.
[3]	EBI_RST	This bit is the protected bit, It means programming this bit needs to write "59h", "16h" "88h" to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100
		1 = EBI controller reset
		0 = EBI controller normal operation
		PDMA Controller Reset (write-protection bit in NUC130/NUC140)
5		Setting this bit to 1 will generate a reset signal to the PDMA. User need to set this bit to 0 to release from reset state.
[2]	PDMA_RST	This bit is the protected bit, It means programming this bit needs to write "59h", "16h" "88h" to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100.
2		1 = PDMA controller reset
She ?	10	0 = PDMA controller normal operation
222	10	CPU kernel one shot reset (Write-protection Bit)
° Q	3 an	Setting this bit will only reset the CPU kernel and Flash Memory Controller(FMC), and this bit will automatically return to 0 after the 2 clock cycles
[1]	CPU_RST	This bit is the protected bit, It means programming this bit needs to write "59h", "16h" "88h" to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100
	Va	1 = CPU one shot reset
	1	0 = CPU normal operation
[0]	CHIP_RST	CHIP one shot reset (Write-protection Bit)

Setting this bit will reset the whole chip, including CPU kernel and all peripherals, and this bit will automatically return to 0 after the 2 clock cycles.
The CHIP_RST is same as the POR reset, all the chip controllers is reset and the chip setting from flash are also reload.
About the difference between CHIP_RST and SYSRESETREQ, please refer to section 5.2.2
This bit is the protected bit. It means programming this bit needs to write "59h", "16h", "88h" to address 0x5000_0100 to disable register protection. Refer to the register REGWRPROT at address GCR_BA+0x100
1 = CHIP one shot reset
0 = CHIP normal operation

nuvoton

Peripheral Reset Control Register2 (IPRSTC2)

Setting these bits 1 will generate asynchronous reset signals to the corresponding IP controller. Users need to set these bits to 0 to release corresponding IP controller from reset state

Register Write-Protection Control Register (REGWRPROT)

Some of the system control registers need to be protected to avoid inadvertent write and disturb the chip operation. These system control registers are protected after the power on reset till user to disable register protection. For user to program these protected registers, a register protection disable sequence needs to be followed by a special programming. The register protection disable sequence is writing the data "59h", "16h" "88h" to the register REGWRPROT address at 0x5000_0100 continuously. Any different data value, different sequence or any other write to other address during these three data writing will abort the whole sequence.

After the protection is disabled, user can check the protection disable bit at address 0x5000_0100 bit0, 1 is protection disable, and 0 is protection enable. Then user can update the target protected register value and then write any data to the address "0x5000_0100" to enable register protection.

This register is write for disable/enable register protection and read for the REGPROTDIS status

5.2.6 System Timer (SysTick)

The Cortex-M0 includes an integrated system timer, SysTick. SysTick provides a simple, 24-bit clear-on-write, decrementing, wrap-on-zero counter with a flexible control mechanism. The counter can be used as a Real Time Operating System (RTOS) tick timer or as a simple counter.

When system timer is enabled, it will count down from the value in the SysTick Current Value Register (SYST_CVR) to 0, and reload (wrap) to the value in the SysTick Reload Value Register (SYST_RVR) on the next clock cycle, then decrement on subsequent clocks. When the counter transitions to 0, the COUNTFLAG status bit is set. The COUNTFLAG bit clears on reads.

The SYST_CVR value is UNKNOWN on reset. Software should write to the register to clear it to 0 before enabling the feature. This ensures the timer will count from the SYST_RVR value rather than an arbitrary value when it is enabled.

If the SYST_RVR is zero, the timer will be maintained with a current value of zero after it is reloaded with this value. This mechanism can be used to disable the feature independently from the timer enable bit.

For more detailed information, please refer to the "ARM[®] Cortex[™]-M0 Technical Reference Manual" and "ARM[®] v6-M Architecture Reference Manual".

	•		CURRE	NT [15:8]	8	SAV	n_
7	6	5	4	3	2	1	0
			CURRE	NT[7:0]		40	20

Bits	Description	
[31:24]	Reserved	Reserved
[23:0]		Current counter value. This is the value of the counter at the time it is sampled. The counter does not provide read-modify-write protection. The register is write-clear. A software write of any value will clear the register to 0.

5.2.7 Nested Vectored Interrupt Controller (NVIC)

The Cortex-M0 provides an interrupt controller as an integral part of the exception mode, named as "Nested Vectored Interrupt Controller (NVIC)". It is closely coupled to the processor kernel and provides following features:

- Nested and Vectored interrupt support
- Automatic processor state saving and restoration
- Reduced and deterministic interrupt latency

The NVIC prioritizes and handles all supported exceptions. All exceptions are handled in "Handler Mode". This NVIC architecture supports 32 (IRQ[31:0]) discrete interrupts with 4 levels of priority. All of the interrupts and most of the system exceptions can be configured to different priority levels. When an interrupt occurs, the NVIC will compare the priority of the new interrupt to the current running one's priority. If the priority of the new interrupt is higher than the current one, the new interrupt handler will override the current handler.

When any interrupts is accepted, the starting address of the interrupt service routine (ISR) is fetched from a vector table in memory. There is no need to determine which interrupt is accepted and branch to the starting address of the correlated ISR by software. While the starting address is fetched, NVIC will also automatically save processor state including the registers "PC, PSR, LR, R0~R3, R12" to the stack. At the end of the ISR, the NVIC will restore the mentioned registers from stack and resume the normal execution. Thus it will take less and deterministic time to process the interrupt request.

The NVIC supports "Tail Chaining" which handles back-to-back interrupts efficiently without the overhead of states saving and restoration and therefore reduces delay time in switching to pending ISR at the end of current ISR. The NVIC also supports "Late Arrival" which improves the efficiency of concurrent ISRs. When a higher priority interrupt request occurs before the current ISR starts to execute (at the stage of state saving and starting address fetching), the NVIC will give priority to the higher one without delay penalty. Thus it advances the real-time capability.

For more detailed information, please refer to the documents "ARM[®] Cortex[™]-M0 Technical Reference Manual" and "ARM[®] v6-M Architecture Reference Manual".

5.2.7.1 Exception Model and System Interrupt Map

Table 5-2 lists the exception model supported by NuMicro[™] NUC100 Series. Software can set four levels of priority on some of these exceptions as well as on all interrupts. The highest user-configurable priority is denoted as "0" and the lowest priority is denoted as "3". The default priority of all the user-configurable interrupts is "0". Note that priority "0" is treated as the fourth priority on the system, after three system exceptions "Reset", "NMI" and "Hard Fault".

Exception Name	Vector Number	Priority
Reset	1 100	-3
NMI	2	-2
Hard Fault	3	Sp Gr
Reserved	4 ~ 10	Reserved
SVCall	11	Configurable
Reserved	12 ~ 13	Reserved
PendSV	14	Configurable
SysTick	15	Configurable
Interrupt (IRQ0 ~ IRQ31)	16 ~ 47	Configurable

5.2.7.2 Vector Table

When any interrupts is accepted, the processor will automatically fetch the starting address of the interrupt service routine (ISR) from a vector table in memory. For ARMv6-M, the vector table base address is fixed at 0x00000000. The vector table contains the initialization value for the stack pointer on reset, and the entry point addresses for all exception handlers. The vector number on previous page defines the order of entries in the vector table associated with exception handler entry as illustrated in previous section.

Vector Table Word Offset	Description
0	SP_main – The Main stack pointer
Vector Number	Exception Entry Pointer using that Vector Number

Table 5-4 Vector Table Format

5.2.7.3 Operation Description

NVIC interrupts can be enabled and disabled by writing to their corresponding Interrupt Set-Enable or Interrupt Clear-Enable register bit-field. The registers use a write-1-to-enable and write-1-to-clear policy, both registers reading back the current enabled state of the corresponding interrupts. When an interrupt is disabled, interrupt assertion will cause the interrupt to become Pending, however, the interrupt will not activate. If an interrupt is Active when it is disabled, it remains in its Active state until cleared by reset or an exception return. Clearing the enable bit prevents new activations of the associated interrupt.

NVIC interrupts can be pended/un-pended using a complementary pair of registers to those used to enable/disable the interrupts, named the Set-Pending Register and Clear-Pending Register respectively. The registers use a write-1-to-enable and write-1-to-clear policy, both registers reading back the current pended state of the corresponding interrupts. The Clear-Pending Register has no effect on the execution status of an Active interrupt.

NVIC interrupts are prioritized by updating an 8-bit field within a 32-bit register (each register supporting four interrupts).

The general registers associated with the NVIC are all accessible from a block of memory in the System Control Space and will be described in next section.

5.2.7.4 NVIC Control Registers

5.2.7.5 Interrupt Source Control Registers

Besides the interrupt control registers associated with the NVIC, the NuMicro™ NUC100 Series also implement some specific control registers to facilitate the interrupt functions, including "interrupt source identification", "NMI source selection" and "interrupt test mode". They are described as below.

Register	Offset	R/W	Description	Reset Value

Bits	Description					
		MCU IRQ Source Register				
		The MCU_IRQ collects all the interrupts from the peripherals and generates the synchronous interrupt to Cortex-M0. There are two modes to generate interrupt to Cortex-M0, the normal mode and test mode.				
[31:0]	MCU_IRQ	The MCU_IRQ collects all interrupts from each peripheral and synchronizes them then interrupts the Cortex-M0.				
		When the MCU_IRQ[n] is 0: Set MCU_IRQ[n] 1 will generate an interrupt to Cortex_MC NVIC[n].				
		When the MCU_IRQ[n] is 1 (mean an interrupt is assert), set 1 to the MCU_IRQ[n] will clear the interrupt and set MCU_IRQ[n] 0 : no any effect				

5.2.8 System Control Register

Cortex-M0 status and operating mode control are managed by System Control Registers. Including CPUID, Cortex-M0 interrupt priority and Cortex-M0power management can be controlled through these system control register

For more detailed information, please refer to the documents "ARM[®] Cortex[™]-M0 Technical Reference Manual" and "ARM[®] v6-M Architecture Reference Manual".

7	6	5	4	3	2	1	0
Rese	erved		VECTACTIVE[5:0]				

Bits	Bits Description				
		NMI set-pending bit			
		Write:			
		0 = no effect			
		1 = changes NMI exception state to pending.			
[31]	NMIPENDSET	Read:			
[0.]		0 = NMI exception is not pending			
		1 = NMI exception is pending.			
		Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it detects a write of 1 to this bit. Entering the handler then clears this bit to 0. This means a read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler.			
[30:29]	Reserved	Reserved			
26		PendSV set-pending bit.			
X.		Write:			
2 2	53	0 = no effect			
[28]	PENDSVSET	1 = changes PendSV exception state to pending.			
[20]	FENDSVSET	Read:			
6	To Co.	0 = PendSV exception is not pending			
	Sall	1 = PendSV exception is pending.			
	20 6	Writing 1 to this bit is the only way to set the PendSV exception state to pending.			
	6	PendSV clear-pending bit.			
[27]	PENDSVCLR	Write:			
	(9)	0 = no effect			

nuvoTon

		1 = removes the pending state from the PendSV exception.
		This is a write only bit. When you want to clear PENDSV bit, you must "write 0 to PENDSVSET and write 1 to PENDSVCLR" at the same time.
		SysTick exception set-pending bit.
		Write:
		0 = no effect
[26]	PENDSTSET	1 = changes SysTick exception state to pending.
		Read:
		0 = SysTick exception is not pending
		1 = SysTick exception is pending.
		SysTick exception clear-pending bit.
	PENDSTCLR	Write:
[25]		0 = no effect
[=0]		1 = removes the pending state from the SysTick exception.
		This is a write only bit. When you want to clear PENDST bit, you must "write 0 to PENDSTSET and write 1 to PENDSTCLR" at the same time.
[24]	Reserved	Reserved
[00]		If set, a pending exception will be serviced on exit from the debug halt state.
[23]	ISRPREEMPT	This is a read only bit.
		Interrupt pending flag, excluding NMI and Faults:
[22]	ISRPENDING	0 = interrupt not pending
[22]	ISKPENDING	1 = interrupt pending.
		This is a read only bit.
[21:18]	Reserved	Reserved
		Indicates the exception number of the highest priority pending enabled exception:
[17:12]	VECTPENDING	0 = no pending exceptions
		Nonzero = the exception number of the highest priority pending enabled exception.
[11:6]	Reserved	Reserved
		Contains the active exception number
[5:0]	VECTACTIVE	0 = Thread mode

							<u>78</u>

Bits	Description	Description				
[31:5]	Reserved	Reserved				
		Send Event on Pending bit:				
		0 = only enabled interrupts or events can wakeup the processor, disabled interrupts are excluded				
[4]	SEVONPEND	1 = enabled events and all interrupts, including disabled interrupts, can wakeup the processor.				
		When an event or interrupt enters pending state, the event signal wakes up the processor from WFE. If the processor is not waiting for an event, the event is registered and affects the next WFE.				
		The processor also wakes up on execution of an SEV instruction or an external event.				
[3]	Reserved	Reserved				
		Controls whether the processor uses sleep or deep sleep as its low power mode:				
[2]	SLEEPDEEP	0 = sleep				
a the		1 = deep sleep				
1 2 3	16.	Indicates sleep-on-exit when returning from Handler mode to Thread mode:				
Sol X	195	0 = do not sleep when returning to Thread mode.				
[1]	SLEEPONEXIT	1 = enter sleep, or deep sleep, on return from an ISR to Thread mode.				
Q	n as	Setting this bit to 1 enables an interrupt driven application to avoid returning to an empty main application.				
[0]	Reserved	Reserved

5.3 Clock Controller

5.3.1 Overview

The clock controller generates the clocks for the whole chip, including system clocks and all peripheral clocks. The clock controller also implements the power control function with the individually clock ON/OFF control, clock source selection and a clock divider. The chip will not enter Power-down mode until CPU sets the power down enable bit (PWR_DOWN_EN) and Cortex-M0 core executes the WFI instruction. After that, chip enters Power-down mode and wait for wake-up interrupt source triggered to leave Power-down mode. In Power-down mode, the clock controller turns off the external 4~24 MHz high speed crystal and internal 22.1184 MHz high speed oscillator to reduce the overall system power consumption.

nuvoTon

Figure 5-4 Clock Generator Global View Diagram

nuvoton

5.3.2 Clock Generator

The clock generator consists of 5 clock sources which are listed below:

- One external 32.768 kHz low speed crystal
- One external 4~24 MHz high speed crystal
- One programmable PLL FOUT(PLL source consists of external 4~24 MHz high speed crystal and internal 22.1184 MHz high speed oscillator)
- One internal 22.1184 MHz high speed oscillator
- One internal 10 kHz low speed oscillator

Figure 5-5 Clock Generator Block Diagram

5.3.3 System Clock and SysTick Clock

The system clock has 5 clock sources which were generated from clock generator block. The clock source switch depends on the register HCLK_S (CLKSEL0[2:0]). The block diagram is shown in Figure 5-6.

Figure 5-6 System Clock Block Diagram

The clock source of SysTick in Cortex-M0 core can use CPU clock or external clock (SYST_CSR[2]). If using external clock, the SysTick clock (STCLK) has 5 clock sources. The clock source switch depends on the setting of the register STCLK_S (CLKSEL0[5:3]). The block diagram is shown in Figure 5-7.

Figure 5-7 SysTick Clock Control Block Diagram

nuvoton

5.3.4 Peripherals Clock

The peripherals clock had different clock source switch setting which depends on the different peripheral. Please refer the CLKSEL1 and CLKSEL2 register description in 5.3.7.

5.3.5 Power-down Mode Clock

When chip enters into Power-down mode, system clocks, some clock sources, and some peripheral clocks will be disabled. Some clock sources and peripherals clock are still active in Power-down mode.

The clocks still active are listed below:

- Clock Generator
 - Internal 10 kHz low speed oscillator clock
 - External 32.768 kHz low speed crystal clock
- Peripherals Clock (When these IP adopt external 32.768 kHz low speed crystal or 10 kHz low speed oscillator as clock source)

5.3.6 Frequency Divider Output

This device is equipped a power-of-2 frequency divider which is composed by16 chained divideby-2 shift registers. One of the 16 shift register outputs selected by a sixteen to one multiplexer is reflected to CLKO function pin. Therefore there are 16 options of power-of-2 divided clocks with the frequency from $F_{in}/2^{1}$ to $F_{in}/2^{16}$ where Fin is input clock frequency to the clock divider.

The output formula is $F_{out} = F_{in}/2^{(N+1)}$, where F_{in} is the input clock frequency, F_{out} is the clock divider output frequency and N is the 4-bit value in FSEL (FRQDIV[3:0]).

When writing 1 to DIVIDER_EN (FRQDIV[4]), the chained counter starts to count. When writing 0 to DIVIDER_EN (FRQDIV[4]), the chained counter continuously runs till divided clock reaches low state and stay in low state.

Bits	Description	
[31:9]	Reserved	Reserve
		This Bit Control the Power Down Entry Condition (Write-protection Bit)
[8]	PD_WAIT_CPU	1 = Chip enters Power-down mode when the both PD_WAIT_CPU and PWR_DOWN_EN bits are set to 1 and CPU run WFI instruction.
S		0 = Chip enters Power-down mode when the PWR_DOWN_EN bit is set to 1
324		System Power Down Enable Bit (Write-protection Bit)
ZY.	e l	When this bit is set to 1, the Power-down mode is enabled and chip power down behavior will depend on the PD_WAIT_CPU bit
0.4	ž	(a) If the PD_WAIT_CPU is 0, then the chip enters Power-down mode immediately after the PWR_DOWN_EN bit set.
C	200	(b) if the PD_WAIT_CPU is 1, then the chip keeps active till the CPU sleep mode is also active and then the chip enters Power-down mode
[7]	PWR_DOWN_EN	When chip wakes up from Power-down mode, this bit is auto cleared. Users need to set this bit again for next power down.
	~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~~	In Power-down mode, external 4~24 MHz high speed crystal and the internal 22.1184 MHz high speed oscillator will be disabled in this mode, but the external 32.768 kHz low speed crystal and internal 10 kHz low speed oscillator are not controlled by Power-down mode.
	No.	In Power-down mode, the PLL and system clock are disabled, and ignored the clock source selection. The clocks of peripheral are not controlled by Power-down mode, if the peripheral clock source is from external 32.768 kHz low speed crystal or the

		internal 10 kHz low speed oscillator.
		1 = Chip enters the Power-down mode instant or wait CPU sleep command WFI
		0 = Chip operating normally or chip in idle mode because of WFI command
		Power-down Mode Wake-up Interrupt Status
		Set by "power down wake-up event", it indicates that resume from Power-down mode"
[6]	PD_WU_STS	The flag is set if the GPIO, USB, UART, WDT, CAN, ACMP, BOD or RTC wake-up occurred
		Write 1 to clear the bit to 0.
		Note: This bit is working only if PD_WU_INT_EN (PWRCON[5]) set to 1.
		Power-down Mode Wake-up Interrupt Enable (Write-protection Bit)
		0 = Disabled
[5]	PD_WU_INT_EN	1 = Enabled
		The interrupt will occur when both PD_WU_STS and PD_WU_INT_EN are high.
		Enable the Wake-up Delay Counter (Write-protection Bit)
		When the chip wakes up from Power-down mode, the clock control will delay certain clock cycles to wait system clock stable.
[4]	PD_WU_DLY	The delayed clock cycle is 4096 clock cycles when chip work at external 4~24 MHz high speed crystal, and 256 clock cycles when chip work at internal 22.1184 MHz high speed oscillator.
		1 = Clock cycles delay Enabled
		0 = Clock cycles delay Disabled
		Internal 10 kHz Low Speed Oscillator Enable (Write-protection Bit)
[3]	OSC10K_EN	1 = Internal 10 kHz low speed oscillator Enabled
		0 = Internal 10 kHz low speed oscillator Disabled
		Internal 22.1184 MHz High Speed Oscillator Enable (Write-protection Bit)
[2]	OSC22M_EN	1 = Internal 22.1184 MHz high speed oscillator Enabled
		0 = Internal 22.1184 MHz high speed oscillator Disabled
		External 32.768 kHz Low Speed Crystal Enable (Write-protection Bit)
[1]	XTL32K_EN	1 = External 32.768 kHz low speed crystal Enabled (Normal operation)
96.		0 = External 32.768 kHz low speed crystal Disabled
Sec. 19		External 4~24 MHz High Speed Crystal Enable (Write-protection Bit)
[0]	XTL12M_EN	The default bit value is set by flash controller user configuration register config0 [26:24]. When the default clock source is from external 4~24 MHz high speed crystal, this bit is set to 1 automatically
Nav	12	1 = External 4~24 MHz high speed crystal Enabled
2/2		0 = External 4~24 MHz high speed crystal Disabled

Register/Instruction	PWR_DOWN_EN	PD_WAIT_CPU	CPU run WFI instruction	Clock Disable
Normal Operation	0	0	NO	All clocks are disabled by control register
Idle Mode (CPU Entry Sleep Mode)	0	x W	YES	Only CPU clock is disabled
Power-down Mode	1	0	NO	Most clocks are disabled except 10 kHz/32.768 kHz, only RTC/WDT/Timer/PWM peripheral clock are still enabled.
Power-down Mode (CPU Entry Deep Sleep Mode)	1	1	YES	Most clocks are disabled except 10 kHz/32.768 kHz, only RTC/WDT/Timer/PWM peripheral clock are still enabled.

Table 5-5 Power-down Mode Control Table

When chip enters Power-down mode, user can wake up chip by some interrupt sources. User should enable related interrupt sources and NVIC IRQ enable bits (NVIC_ISER) before set PWR_DOWN_EN bit in PWRCON[7] to ensure chip can enter power down and be woken-up successfully.

#### AHB Devices Clock Enable Control Register (AHBCLK)

These bits for this register are used to enable/disable clock for system clock PDMA clock and EBI clock.

### 5.4 USB Device Controller (USB)

#### 5.4.1 Overview

There is one set of USB 2.0 full-speed device controller and transceiver in this device, which is compliant with the USB 2.0 full-speed device specification and supports control/bulk/interrupt/ isochronous transfer types.

In this device controller, there are two main interfaces: APB bus and USB bus that come from the USB PHY transceiver. For the APB bus, the CPU can program control registers through it. There are 512 bytes internal SRAM as data buffer in this controller. For IN or OUT transfer, it is necessary to write data to SRAM or read data from SRAM through the APB interface or SIE. Users need to set the effective starting address of SRAM for each endpoint buffer through "buffer segmentation register (USB_BUFSEGx)".

There are 6 endpoints in this controller. Each of the endpoint can be configured as IN or OUT endpoint. All the operations including Control, Bulk, Interrupt and Isochronous transfer are implemented in this block. The block of ENDPOINT CONTROL is also used to manage the data sequential synchronization, endpoint states, current start address, transaction status, and data buffer status for each endpoint.

There are four different interrupt events in this controller, including wake-up function, device plugin or plug-out event, USB events, such as IN ACK, OUT ACK etc, and BUS events, such as suspend and resume, etc. Any event will cause an interrupt, and users just need to check the related event flags in interrupt event status register (USB_INTSTS) to acknowledge what kind of interrupt occurring, and then check the related USB Endpoint Status Register (USB_EPSTS) to acknowledge what kind of event occurring in this endpoint.

A software-disable function is also supported for this USB controller. It is used to simulate the disconnection of this device from the host. If user enables DRVSE0 bit (USB_DRVSE0), the USB controller will force the output of USB_DP and USB_DM to level low and its function is disabled. After the DRVSE0 bit is disabled, host will enumerate the USB device again.

Also refer to Universal Serial Bus Specification Revision 1.1.

#### 5.4.2 Features

This Universal Serial Bus (USB) performs a serial interface with a single connector type for attaching all USB peripherals to the host system. Following is the feature listing of this USB.

- Compliant with USB 2.0 Full-Speed specification
- Provides 1 interrupt vector with 4 different interrupt events (WAKEUP, FLDET, USB and BUS)
- Supports Control/Bulk/Interrupt/Isochronous transfer type
- Supports suspend function when no bus activity existing for 3 ms
- Provides 6 endpoints for configurable Control/Bulk/Interrupt/Isochronous transfer types and maximum 512 bytes buffer size
- Provides remote wake-up capability

### 5.4.3 Block Diagram

Figure 5-10 USB Block Diagram

#### 5.4.4 Functional Description

#### 5.4.4.1 SIE (Serial Interface Engine)

The Serial Interface Engine (SIE) is the front-end of the device controller and handles most of the USB packet protocol. The SIE typically comprehends signaling up to the transaction level. The functions that the SIE handles include:

- Packet recognition, transaction sequencing
- SOP, EOP, RESET, RESUME signal detection/generation
- Clock/Data separation
- NRZI Data encoding/decoding and bit-stuffing
- CRC generation and checking (for Token and Data)
- Packet ID (PID) generation and checking/ decoding
- Serial-Parallel/ Parallel-Serial conversion

#### 5.4.4.2 Endpoint Control

There are 6 endpoints in the controller. Each of the endpoints can be configured as Control, Bulk, Interrupt, or Isochronous transfer type. All the operations including Control, Bulk, Interrupt and Isochronous transfer are implemented in this block. It is also used to manage the data sequential synchronization, endpoint state control, current endpoint start address, current transaction status, and data buffer status in each endpoint.

#### 5.4.4.3 Digital Phase Lock Loop

The bit rate of USB data is 12 MHz. The DPLL use the 48 MHz which comes from the clock controller to lock the input data RXDP and RXDM. The 12 MHz bit rate clock is also converted from DPLL.

#### 5.4.4.4 Floating De-bounce

A USB device may be plug-in or plug-out from the USB host. In order to monitor the state of a USB device when it is detached from the USB host, the device controller provides hardware debounce for USB floating detect interrupt to avoid bounce problems on USB plug-in or unplug. Floating detect interrupt appears about 10 ms later than USB plug-in or plug-out. A user can acknowledge USB plug-in/plug-out by reading register "USB_FLDET". The flag in "FLDET" represents the current state on the bus without de-bounce. If the FLDET is 1, it means the controller has plug-in the USB. If the user polling this flag to check USB state, he/she must add software de-bounce if necessary.

#### 5.4.4.5 Interrupt

This USB provides 1 interrupt vector with 4 interrupt events (WAKEUP, FLDET, USB and BUS). The WAKEUP event is used to wake-up the system clock when Power-down mode is enabled. (The power mode function is defined in system power down control register, PWRCON). The FLDET event is used for USB plug-in or unplug. The USB event notifies users of some USB requests, such as IN ACK, OUT ACK etc., and the BUS event notifies users of some bus events, like suspend, resume, etc. User must set related bits in the interrupt enable register (USB_INTEN) of USB Device Controller to enable USB interrupts.

Wake-up interrupt is only present when the chip enters Power-down mode and then wake-up event had happened. After the chip enters Power-down mode, any change on USB_DP and USB_DM can wake-up this chip (provided that USB wake-up function is enabled). If this change is not intentionally, no interrupt but wake-up interrupt will occur. After USB wake-up, this interrupt will occur when no other USB interrupt events are present for more than 20ms. The following figure is the control flow of wake-up interrupt.

Figure 5-11 Wake-up Interrupt Operation Flow

USB interrupt is used to notify users of any USB event on the bus, and a user can read EPSTS (USB_EPSTS[25:8]) and EPEVT5~0 (USB_INTSTS[21:16]) to know what kind of request is to which endpoint and take necessary responses.

Same as USB interrupt, BUS interrupt notifies users of some bus events, like USB reset, suspend, time-out, and resume. A user can read USB_ATTR to acknowledge bus events.

#### 5.4.4.6 Power Saving

USB turns off PHY transceiver automatically to save power while this chip enters Power-down mode. Furthermore, a user can write 0 into USB_ATTR[4] to turn off PHY under special circumstances like suspend to save power.

#### 5.4.4.7 Buffer Control

There is 512 bytes SRAM in the controller and the 6 endpoints share this buffer. The user shall configure each endpoint's effective starting address in the buffer segmentation register before the USB function active. The BUFFER CONTROL block is used to control each endpoint's effective starting address and its SRAM size is defined in the MXPLD register.

Figure 5-12 depicts the starting address for each endpoint according the content of USB_BUFSEGx and USB_MXPLDx registers. If the USB_BUFSEG0 is programmed as 0x08h and USB_MXPLD0 is set as 0x40h, the SRAM size of endpoint 0 is start from USB_BA+0x108h and end in USB_BA+0x148h. (**Note:** the USB SRAM base is USB_BA+0x100h).

	USB SRAM Start Address	USB SRAM = USB_BA + 0x0100h	~
	Setup Token Buffer: 8 bytes	20	0
BUFSEG0 = 0x008	EP0 SRAM Buffer: 64 bytes	EP0 SA = USB_BA + 0x0108h MXPLD0 = 0x40	
BUFSEG1 = 0x048	EP1 SRAM Buffer: 64 bytes	EP1 SA = USB_BA + 0x0148h MXPLD1 = 0x40	Con la la
BUFSEG2 = 0x088	EP2 SRAM Buffer	EP2 SA = USB_BA + 0x0188h	512 Bytes
BUFSEG3 = 0x100	EP3 SRAM Buffer	EP3 SA = USB_BA + 0x0200h	

Figure 5-12 Endpoint SRAM Structure

#### 5.4.4.8 Handling Transactions with USB Device Peripheral

User can use interrupt or polling USB_INTSTS to monitor the USB Transactions, when transactions occur, USB_INTSTS will be set by hardware and send an interrupt request to CPU (if related interrupt enabled), or user can polling USB_INTSTS to get these events without interrupt. The following is the control flow with interrupt enable.

When USB host has requested data from device controller, users need to prepare related data into the specified endpoint buffer in advance. After buffering the required data, users need to write the actual data length in the specified MAXPLD register. Once this register is written, the internal signal "In_Rdy" will be asserted and the buffering data will be transmitted immediately after receiving associated IN token from Host. Note that after transferring the specified data, the signal "In_Rdy" will de-assert automatically by hardware.

Figure 5-13 Setup Transaction followed by Data in Transaction

Alternatively, when USB host wants to transmit data to the OUT endpoint in the device controller, hardware will buffer these data to the specified endpoint buffer. After this transaction is completed, hardware will record the data length in related MAXPLD register and de-assert the signal "Out_Rdy". This will avoid hardware accepting next transaction until users move out current data in the related endpoint buffer. Once users have processed this transaction, the related register "MAXPLD" needs to be written by firmware to assert the signal "Out_Rdy" again to accept next transaction.

Figure 5-14 Data Out Transfer

		Endpoint 5's USB Event Status
[21]	EPEVT5	1 = USB event occurred on Endpoint 5, check USB_EPSTS[25:23] to know which kind of USB event was occurred, cleared by write 1 to USB_INTSTS[21] or USB_INTSTS[1]
		0 = No event occurred in endpoint 5
		Endpoint 4's USB Event Status
[20]	EPEVT4	1 = USB event occurred on Endpoint 4, check USB_EPSTS[22:20] to know which kind of USB event was occurred, cleared by write 1 to USB_INTSTS[20] or USB_INTSTS[1]
Xx		0 = No event occurred in endpoint 4
P.G	2	Endpoint 3's USB Event Status
[19]	EPEVT3	1 = USB event occurred on Endpoint 3, check USB_EPSTS[19:17] to know which kind of USB event was occurred, cleared by write 1 to USB_INTSTS[19] or USB_INTSTS[1]
N	2 Sh	0 = No event occurred in endpoint 3
	200 00	Endpoint 2's USB Event Status
[18]	EPEVT2	1 = USB event occurred on Endpoint 2, check USB_EPSTS[16:14] to know which kind of USB event was occurred, cleared by write 1 to USB_INTSTS[18] or USB_INTSTS[1]
	2	0 = No event occurred in endpoint 2

Endpoint 1's USB Event Status
1 = USB event occurred on Endpoint 1, check USB_EPSTS[13:11] to know which kind of USB event was occurred, cleared by write 1 to USB_INTSTS[17] or USB_INTSTS[1]
0 = No event occurred in endpoint 1
Endpoint 0's USB Event Status
1 = USB event occurred on Endpoint 0, check USB_EPSTS[10:8] to know which kind of USB event was occurred, cleared by write 1 to USB_INTSTS[16] or USB_INTSTS[1]
0 = No event occurred in endpoint 0
Reserved
Wake-up Interrupt Status
P_STS 1 = Wake-up event occurred, cleared by write 1 to USB_INTSTS[3]
0 = No Wake-up event is occurred
Floating Detected Interrupt Status
STS 1 = There is attached/detached event in the USB bus and it is cleared by write 1 to USB_INTSTS[2].
0 = There is not attached/detached event in the USB
USB event Interrupt Status
The USB event includes the Setup Token, IN Token, OUT ACK, ISO IN, or ISO OUT events in the bus.
S 1 = USB event occurred, check EPSTS0~5[2:0] to know which kind of USB event was occurred, cleared by write 1 to USB_INTSTS[1] or EPSTS0~5 and SETUP (USB_INTSTS[31])
0 = No any USB event is occurred
BUS Interrupt Status
The BUS event means that there is one of the suspense or the resume function in the bus.
S 1 = Bus event occurred; check USB_ATTR[3:0] to know which kind of bus event was occurred, cleared by write 1 to USB_INTSTS[0].

5.5 General Purpose I/O (GPIO)

5.5.1 Overview

The NuMicro[™] NUC130/NUC140 has up to 80 General Purpose I/O pins that can be shared with other function pins depending on the chip configuration. These 80 pins are arranged in 5 ports named with GPIOA, GPIOB, GPIOC, GPIOD and GPIOE. Each port has maximum 16 pins. Each one of the 80 pins is independent and has the corresponding register bits to control the pin mode function and data.

The I/O type of each of I/O pins can be configured by software individually as input, output, opendrain or quasi-bidirectional mode. After reset, the I/O type of all pins stay in quasi-bidirectional mode and port data register GPIOx_DOUT[15:0] resets to 0x0000_FFFF. Each I/O pin has a very weak individual pull-up resistor which is about 110 K Ω ~300 K Ω for V_{DD} is from 5.0 V to 2.5 V.

5.5.2 Features

- Four I/O modes:
 - Quasi bi-direction
 - Push-Pull output
 - Open-Drain output
 - Input only with high impendence
- TTL/Schmitt trigger input selectable
- I/O pin configured as interrupt source with edge/level setting
- Supports High Driver and High Sink I/O mode

5.5.3 Functional Description

5.5.3.1 Input Mode Explanation

Set GPIOx_PMD (PMDn[1:0]) to 00b the GPIOx port [n] pin is in Input mode and the I/O pin is in tri-state (high impedance) without output drive capability. The GPIOx_PIN value reflects the status of the corresponding port pins.

5.5.3.2 Output Mode Explanation

Set GPIOx_PMD (PMDn[1:0]) to 01b the GPIOx port [n] pin is in Output mode and the I/O pin supports digital output function with source/sink current capability. The bit value in the corresponding bit [n] of GPIOx_DOUT is driven on the pin.

nuvoton

5.5.3.3 Open-Drain Mode Explanation

Set GPIOx_PMD (PMDn[1:0]) to 10b the GPIOx port [n] pin is in Open-Drain mode and the digital output function of I/O pin supports only sink current capability, an additional pull-up resistor is needed for driving high state. If the bit value in the corresponding bit [n] of GPIOx_DOUT is 0, the pin drive a "low" output on the pin. If the bit value in the corresponding bit [n] of GPIOx_DOUT is 1, the pin output drives high that is controlled by external pull high resistor.

Figure 5-16 Open-Drain Output

5.5.3.4 Quasi-bidirectional Mode Explanation

Set GPIOx_PMD (PMDn[1:0]) to 11b the GPIOx port [n] pin is in Quasi-bidirectional mode and the I/O pin supports digital output and input function at the same time but the source current is only up to hundreds uA. Before the digital input function is performed the corresponding bit in GPIOx_DOUT must be set to 1. The quasi-bidirectional output is common on the 80C51 and most of its derivatives. If the bit value in the corresponding bit [n] of GPIOx_DOUT is 0, the pin drive a "low" output on the pin. If the bit value in the corresponding bit [n] of GPIOx_DOUT is 1, the pin will check the pin value. If pin value is high, no action takes. If pin state is low, then pin will drive strong high with 2 clock cycles on the pin and then disable the strong output drive and then the pin status is control by internal pull-up resistor. Note that the source current capability in quasibidirectional mode is only about 200 uA to 30 uA for V_{DD} is form 5.0 V to 2.5 V.

5.5.3.5 GPIO Interrupt and wakeup function

Each GPIO pin can be set as chip interrupt source by setting correlative GPIOx_IEN bit and GPIOx_IMD. There are four types of interrupt condition can be selected: low level trigger, high level trigger, falling edge trigger and rising edge trigger. For edge trigger condition, user can enable input signal de-bounce function to prevent unexpected interrupt happened which caused by noise. The de-bounce clock source and sampling cycle can be set through DEBOUNCE register.

The GPIO can also be the chip wakeup source when chip enters Idle mode or Power-down mode. The setting of wakeup trigger condition is the same as GPIO interrupt trigger, but there are two things need to be noticed if using GPIO as chip wakeup source

1. To ensure the I/O status before entering Power-down mode

If using toggle GPIO to wakeup system, user must to make sure the I/O status before entering to idle mode or Power-down mode according to the relative wakeup settings.

For example, if configure the wakeup event occurred by I/O rising edge/high level trigger, user must make sure the I/O status of specified pin is at low level before entering to idle/Power-down mode; and if configure I/O falling edge/low level trigger to trigger a wakeup event, user must make sure the I/O status of specified pin is at high level before entering to Power-down mode.

2. To disable the specified I/O de-bounce function if necessary

If the specified wakeup GPIO with input signal de-bounce function, the de-bounce function must be disabled before system enters Power-down mode, otherwise system will encounter two GPIO interrupts when system wakeup (One is cause by wakeup function, the other one is caused by debounce function).

Bits	Description					
[31:16]	Reserved	Reserved				
		Port [A/B/C/D/E] Data Output Write Mask				
		These bits are used to protect the corresponding register of GPIOx_DOUT bit[n]. When set the DMASK bit[n] to 1, the corresponding GPIOx_DOUT[n] bit is protected. The write signal is masked, write data to the protect bit is ignored				
[n] n=0.115	DMASK	1 = The corresponding GPIOx_DOUT[n] bit is protected				
		0 = The corresponding GPIOx_DOUT[n] bit can be updated				
志		Note: This function only protect corresponding GPIOx_DOUT[n] bit, and will not protect corresponding bit control register (GPIOAx_DOUT, GPIOBx_DOUT, GPIOCx_DOUT, GPIODx_DOUT, GPIOEx_DOUT).

[0]	Pxn_PDIO	GPIO Px.n Pin Data I/O         Write this bit can control one GPIO pin output value         1 = Set corresponding GPIO pin to high         0 = Set corresponding GPIO pin to low         Read this register to get GPIO pin status.         For example: write PA0_PDIO will reflect the written value to bit GPIOA_DOUT[0], read PA0_PDIO will return the value of GPIOA_PIN[0]         Note: The write operation will not be affected by register GPIOx_DMASK

#### 5.6 I²C Serial Interface Controller (Master/Slave) (I²C)

#### 5.6.1 Overview

 $I^2C$  is a two-wire, bi-directional serial bus that provides a simple and efficient method of data exchange between devices. The  $I^2C$  standard is a true multi-master bus including collision detection and arbitration that prevents data corruption if two or more masters attempt to control the bus simultaneously.

Data is transferred between a Master and a Slave synchronously to SCL on the SDA line on a byte-by-byte basis. Each data byte is 8-bit long. There is one SCL clock pulse for each data bit with the MSB being transmitted first. An acknowledge bit follows each transferred byte. Each bit is sampled during the high period of SCL; therefore, the SDA line may be changed only during the low period of SCL and must be held stable during the high period of SCL. A transition on the SDA line while SCL is high is interpreted as a command (START or STOP). Please refer to Figure 5-18 for more detailed I²C BUS Timing.

Figure 5-18 I²C Bus Timing

The device's on-chip  $I^2C$  logic provides the serial interface that meets the  $I^2C$  bus standard mode specification. The  $I^2C$  port handles byte transfers autonomously. To enable this port, the bit ENS1 in I2CON should be set to '1'. The  $I^2C$  H/W interfaces to the  $I^2C$  bus via two pins: SDA and SCL.

Pull up resistor is needed for  $I^2C$  operation as these are open drain pins. When the I/O pins are used as  $I^2C$  port, user must set the pins function to  $I^2C$  in advance.

#### 5.6.2 Features

The I²C bus uses two wires (SDA and SCL) to transfer information between devices connected to the bus. The main features of the bus are:

- Master/Slave mode
- Bidirectional data transfer between masters and slaves
- Multi-master bus (no central master)
- Arbitration between simultaneously transmitting masters without corruption of serial data on the bus
- Serial clock synchronization allows devices with different bit rates to communicate via one serial bus
- Serial clock synchronization can be used as a handshake mechanism to suspend and resume serial transfer
- Built-in a 14-bit time-out counter will request the I²C interrupt if the I²C bus hangs up and timer-out counter overflows.
- External pull-up are needed for high output
- Programmable clocks allow versatile rate control
- Supports 7-bit addressing mode
- I²C-bus controllers support multiple address recognition (Four slave address with mask option)

#### 5.6.3 Functional Description

#### 5.6.3.1 ^PC Protocol

Normally, a standard communication consists of four parts:

- 1) START or Repeated START signal generation
- 2) Slave address and R/W bit transfer
- 3) Data transfer
- 4) STOP signal generation

#### Figure 5-19 I²C Protocol

#### 5.6.3.2 Data transfer on the ²C-bus

錯誤! 找不到參照來源。 shows a master transmits data to slave. A master addresses a slave with a 7-bit address and 1-bit write index to denote master wants to transmit data to slave. The master keep transmitting data after slave returns acknowledge to master.

Figure 5-20 Master Transmits Data to Slave

錯誤! 找不到参照來源。 shows a master read data from slave. A master addresses a slave with a 7-bit address and 1-bit read index to denote master wants to read data from slave. The slave will start transmitting data after slave returns acknowledge to master.

Figure 5-21 Master Reads Data from Slave

#### 5.6.3.3 START or Repeated START signal

When the bus is free/idle, meaning no master device is engaging the bus (both SCL and SDA lines are high), a master can initiate a transfer by sending a START signal. A START signal, usually referred to as the S-bit, is defined as a HIGH to LOW transition on the SDA line while SCL is HIGH. The START signal denotes the beginning of a new data transfer.

A Repeated START (Sr) is no STOP signal between two START signals. The master uses this method to communicate with another slave or the same slave in a different transfer direction (e.g. from writing to a device to reading from a device) without releasing the bus.

#### STOP signal

The master can terminate the communication by generating a STOP signal. A STOP signal, usually referred to as the P-bit, is defined as a LOW to HIGH transition on the SDA line while SCL is HIGH.

Figure 5-22 START and STOP Conditions

#### 5.6.3.4 Slave Address Transfer

The first byte of data transferred by the master immediately after the START signal is the slave address. This is a 7-bit calling address followed by a RW bit. The RW bit signals the slave the data transfer direction. No two slaves in the system can have the same address. Only the slave with an address that matches the one transmitted by the master will respond by returning an acknowledge bit by pulling the SDA low at the 9th SCL clock cycle.

#### 5.6.3.5 Data Transfer

Once successful slave addressing has been achieved, the data transfer can proceed on a byteby-byte basis in the direction specified by the RW bit sent by the master. Each transferred byte is followed by an acknowledge bit on the 9th SCL clock cycle. If the slave signals a Not Acknowledge (NACK), the master can generate a STOP signal to abort the data transfer or generate a Repeated START signal and start a new transfer cycle.

If the master, as the receiving device, does Not Acknowledge (NACK) the slave, the slave releases the SDA line for the master to generate a STOP or Repeated START signal.

Figure 5-23 Bit Transfer on I²C Bus

Figure 5-24 Acknowledge on I²C Bus

## nuvoton

#### 5.6.4 Protocol Registers

The CPU interfaces to the  $I^2$ C port through the following thirteen special function registers: I2CON (control register), I2CSTATUS (status register), I2CDAT (data register), I2CADDRn (address registers, n=0~3), I2CADMn (address mask registers, n=0~3), I2CLK (clock rate register) and I2CTOC (Time-out counter register). All bit 31~ bit 8 of these  $I^2$ C special function registers are reserved. These bits do not have any functions and are all zero if read back.

When  $I^2C$  port is enabled by setting ENS1 (I2CON [6]) to high, the internal states will be controlled by I2CON and  $I^2C$  logic hardware. Once a new status code is generated and stored in I2CSTATUS, the  $I^2C$  Interrupt Flag bit SI (I2CON [3]) will be set automatically. If the Enable Interrupt bit EI (I2CON [7]) is set high at this time, the  $I^2C$  interrupt will be generated. The bit field I2CSTATUS[7:3] stores the internal state code, the lowest 3 bits of I2CSTATUS are always zero and the content keeps stable until SI is cleared by software. The base address is 4002_0000 and 4012_0000.

#### 5.6.4.1 Address Registers (I2 CADDR)

 $I^2C$  port is equipped with four slave address registers I2CADDRn (n=0~3). The contents of the register are irrelevant when  $I^2C$  is in Master mode. In the Slave mode, the bit field I2CADDRn[7:1] must be loaded with the chip's own slave address. The  $I^2C$  hardware will react if the contents of I2CADDRn are matched with the received slave address.

The I²C ports support the "General Call" function. If the GC bit (I2CADDRn [0]) is set the I²C port hardware will respond to General Call address (00H). Clear GC bit to disable general call function.

When GC bit is set and the  $I^2C$  is in Slave mode, it can receive the general call address by 00H after Master send general call address to  $I^2C$  bus, then it will follow status of GC mode.

 $I^2C$  bus controllers support multiple address recognition with four address mask registers I2CADMn (n=0~3). When the bit in the address mask register is set to one, it means the received corresponding address bit is don't-care. If the bit is set to 0, that means the received corresponding register bit should be exact the same as address register.

#### 5.6.4.2 Data Register (I2CDAT)

This register contains a byte of serial data to be transmitted or a byte which just has been received. The CPU can read from or write to this 8-bit (I2CDAT [7:0]) directly while it is not in the process of shifting a byte. when I²C is in a defined state and the serial interrupt flag (SI) is set. Data in I2CDAT [7:0] remains stable as long as SI bit is set. While data is being shifted out, data on the bus is simultaneously being shifted in; I2CDAT [7:0] always contains the last data byte present on the bus. Thus, in the event of arbitration lost, the transition from master transmitter to slave receiver is made with the correct data in I2CDAT [7:0].

I2CDAT [7:0] and the acknowledge bit form a 9-bit shift register, the acknowledge bit is controlled by the I²C hardware and cannot be accessed by the CPU. Serial data is shifted through the acknowledge bit into I2CDAT [7:0] on the rising edges of serial clock pulses on the SCL line. When a byte has been shifted into I2CDAT [7:0], the serial data is available in I2CDAT [7:0], and the acknowledge bit (ACK or NACK) is returned by the control logic during the ninth clock pulse. Serial data is shifted out from I2CDAT [7:0] on the falling edges of SCL clock pulses, and is shifted into I2CDAT [7:0] on the rising edges of SCL clock pulses.

Figure 5-25 I²C Data Shifting Direction

#### 5.6.4.3 Control Register (I2CON)

The CPU can read from and write to this 8-bit field of I2CON [7:0] directly. Two bits are affected by hardware: the SI bit is set when the  $I^2$ C hardware requests a serial interrupt, and the STO bit is cleared when a STOP condition is present on the bus. The STO bit is also cleared when ENS1 = 0.

- EI Enable Interrupt.
- ENS1 Set to enable I²C serial function controller. When ENS1=1 the I²C serial function enables. The Multi Function pin function of SDA and SCL must be set to I²C function.
- STA I²C START Control Bit. Setting STA to logic 1 to enter Master mode, the I²C hardware sends a START or repeat START condition to bus when the bus is free.
- STO I²C STOP Control Bit. In Master mode, setting STO to transmit a STOP condition to bus then I²C hardware will check the bus condition if a STOP condition is detected this flag will be cleared by hardware automatically. In a Slave mode, setting STO resets I²C hardware to the defined "not addressed" Slave mode. This means it is NO LONGER in the slave receiver mode to receive data from the master transmit device.
- SI I²C Interrupt Flag. When a new I²C state is present in the I2CSTATUS register, the SI flag is set by hardware, and if bit EI (I2CON [7]) is set, the I²C interrupt is requested. SI must be cleared by software. Clear SI is by writing 1 to this bit. All states are listed in section 5.6.6
- AA Assert Acknowledge Control Bit. When AA=1 prior to address or data received, an acknowledged (low level to SDA) will be returned during the acknowledge clock pulse on the SCL line when 1.) A slave is acknowledging the address sent from master, 2.) The receiver devices are acknowledging the data sent by transmitter. When AA=0 prior to address or data received, a Not acknowledged (high level to SDA) will be returned during the acknowledge clock pulse on the SCL line.

#### 5.6.4.4 Status Register (I2CSTATUS)

I2CSTATUS [7:0] is an 8-bit read-only register. The three least significant bits are always 0. The bit field I2CSTATUS [7:3] contain the status code. There are 26 possible status codes, All states are listed in section 5.6.6. When I2CSTATUS [7:0] contains F8H, no serial interrupt is requested. All other I2CSTATUS [7:3] values correspond to defined I²C states. When each of these states is entered, a status interrupt is requested (SI = 1). A valid status code is present in I2CSTATUS[7:3] one cycle after SI is set by hardware and is still present one cycle after SI has been reset by software.

In addition, state 00H stands for a Bus Error. A Bus Error occurs when a START or STOP condition is present at an illegal position in the format frame. Examples of illegal positions are during the serial transfer of an address byte, a data byte or an acknowledge bit. To recover  $I^2C$  from bus error, STO should be set and SI should be clear to enter not addressed Slave mode. Then clear STO to release bus and to wait new communication.  $I^2C$  bus can not recognize stop condition during this action when bus error occurs.

	Master Mode		Slave Mode
STATUS	Description	STATUS	Description
0x08	Start	0xA0	Slave Transmit Repeat Start or Stop
0x10	Master Repeat Start	0xA8	Slave Transmit Address ACK
0x18	Master Transmit Address ACK	0xB0	Slave Transmit Arbitration Lost
0x20	Master Transmit Address NACK	0xB8	Slave Transmit Data ACK
0x28	Master Transmit Data ACK	0xC0	Slave Transmit Data NACK
0x30	Master Transmit Data NACK	0xC8	Slave Transmit Last Data ACK
0x38	Master Arbitration Lost	0x60	Slave Receive Address ACK
0x40	Master Receive ACK	0x68	Slave Receive Arbitration Lost
0x48	Master Receive NACK	0x80	Slave Receive Data ACK
0x50	Master Receive ACK	0x88	Slave Receive Data NACK
0x58	Master Receive NACK	0x70	GC mode Address ACK
0x00	Bus error	0x78	GC mode Arbitration Lost
SQ.	62	0x90	GC mode Data ACK
- N		0x98	GC mode Data NACK
0xF8	Bus Released	I	

Note: Status "0xF8" exists in both master/Slave modes, and it won't raise interrupt.

Table 5-6 I²C Status Code Description Table

#### 5.6.4.5 ²C Clock Baud Rate Bits (I2CLK)

The data baud rate of  $I^2C$  is determines by I2CLK [7:0] register when  $I^2C$  is in a Master mode. It is not important when  $I^2C$  is in a Slave mode. In the Slave modes,  $I^2C$  will automatically synchronize with any clock frequency from master  $I^2C$  device.

The data baud rate of  $I^2C$  setting is Data Baud Rate of  $I^2C$  = (system clock) / (4x (I2CLK [7:0] +1)). If system clock = 16 MHz, the I2CLK [7:0] = 40 (28H), so data baud rate of  $I^2C$  = 16 MHz/ (4x (40 +1)) = 97.5 Kbits/sec.

#### 5.6.4.6 The L²C Time-out Counter Register (I2CTOC)

There is a 14-bit time-out counter which can be used to deal with the  $l^2C$  bus hang-up. If the timeout counter is enabled, the counter starts up counting until it overflows (TIF=1) and generates  $l^2C$ interrupt to CPU or stops counting by clearing ENTI to 0. When time-out counter is enabled, setting flag SI to high will reset counter and re-start up counting after SI is cleared. If  $l^2C$  bus hangs up, it causes the I2CSTATUS and flag SI are not updated for a period, the 14-bit time-out counter may overflow and acknowledge CPU the  $l^2C$  interrupt. Refer to the Figure 5-26 for the 14bit time-out counter. User may write 1 to clear TIF to 0.

### 5.6.7 Operation Modes

The on-chip I²C ports support five operation modes, Master transmitter, Master receiver, Slave transmitter, Slave receiver, and GC call.

In a given application, I²C port may operate as a master or as a slave. In Slave mode, the I²C port hardware looks for its own slave address and the general call address. If one of these addresses is detected, and if the slave is willing to receive or transmit data from/to master(by setting the AA bit), acknowledge pulse will be transmitted out on the 9th clock, hence an interrupt is requested on both master and slave devices if interrupt is enabled. When the microcontroller wishes to become the bus master, the hardware waits until the bus is free before the Master mode is entered so that a possible slave action didn't be interrupted. If bus arbitration is lost in the Master mode, I²C port switches to the Slave mode immediately and can detect its own slave address in the same serial transfer.

Bits STA, STO and AA in I2CON register will determine the next state of the  $I^2$ C hardware after SI flag is cleared. Upon completion of the new action, a new status code will be updated and the SI flag will be set. If the  $I^2$ C interrupt control bit EI (I2CON [7]) is set, appropriate action or software branch of the new status code can be performed in the Interrupt service routine.

In the following description of five operation modes, detailed data flow is represented. The legend for those data flow figures is shown in Figure 5-27

Figure 5-27 Legend for the Following Five Figures

#### 5.6.7.1 Master Transmitter Mode

As shown in Figure 5-28, in master transmitter mode, serial data output through SDA while SCL outputs the serial clock. The first byte transmitted contains the slave address of the receiving device (7-bit) and the data direction bit. In this case the data direction bit (R/W) will be logic 0, and it is represented by "W" in the Figure 5-20. Thus the first byte transmitted is SLA+W. Serial data is transmitted 8-bit at a time. After each byte is transmitted, an acknowledge bit is received. START and STOP conditions are output to indicate the beginning and the end of a serial transfer.

Figure 5-28 Master Transmitter Mode

Page 219 of 573

#### 5.6.7.2 Master Receiver Mode

As shown in Figure 5-29, in this case the data direction bit (R/W) will be logic 1, and it is represented by "R" in the Figure 5-21. Thus the first byte transmitted is SLA+R. Serial data is received via SDA while SCL outputs the serial clock. Serial data is received 8-bit at a time. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are output to indicate the beginning and end of a serial transfer.

Figure 5-29 Master Receiver Mode

### nuvoton

#### 5.6.7.3 Slave Receiver Mode

As shown in Figure 5-30, serial data and the serial clock are received through SDA and SCL. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are recognized as the beginning and end of a serial transfer. Address recognition is performed by hardware after reception of the slave address and direction bit.

#### 5.6.7.4 Slave Transmitter Mode

As shown in Figure 5-31, the first byte is received and handled as in the slave receiver mode. However, in this mode, the direction bit will indicate that the transfer direction is reversed. Serial data is transmitted via SDA while the serial clock is input through SCL. START and STOP conditions are recognized as the beginning and end of a serial transfer.

Figure 5-31 Slave Transmitter Mode

#### 5.6.7.5 General Call (GC) Mode

As shown in Figure 5-32, if the GC bit (I2CADDRn [0]) is set, the  $I^2C$  port hardware will respond to General Call address (00H). Clear GC bit to disable general call function. When GC bit is set and the  $I^2C$  is in Slave mode, it can receive the general call address by 00H after Master send general call address to  $I^2C$  bus, then it will follow status of GC mode. Serial data and the serial clock are received through SDA and SCL. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions are recognized as the beginning and end of a serial transfer. Address recognition is performed by hardware after receiption of the slave address and direction bit.

### 5.7 **PWM Generator and Capture Timer (PWM)**

#### 5.7.1 Overview

The NuMicro[™] NUC130/NUC140 has 2 sets of PWM group supports total 4 sets of PWM Generators which can be configured as 8 independent PWM outputs, PWM0~PWM7, or as 4 complementary PWM pairs, (PWM0, PWM1), (PWM2, PWM3), (PWM4, PWM5) and (PWM6, PWM7) with 4 programmable dead-zone generators.

Each PWM Generator has one 8-bit prescaler, one clock divider with 5 divided frequencies (1, 1/2, 1/4, 1/8, 1/16), two PWM Timers including two clock selectors, two 16-bit PWM downcounters for PWM period control, two 16-bit comparators for PWM duty control and one deadzone generator. The 4 sets of PWM Generators provide eight independent PWM interrupt flags which are set by hardware when the corresponding PWM period down counter reaches zero. Each PWM interrupt source with its corresponding enable bit can cause CPU to request PWM interrupt. The PWM generators can be configured as one-shot mode to produce only one PWM cycle signal or auto-reload mode to output PWM waveform continuously.

When PCR.DZEN01 is set, PWM0 and PWM1 perform complementary PWM paired function; the paired PWM period, duty and dead-time are determined by PWM0 timer and Dead-zone generator 0. Similarly, the complementary PWM pairs of (PWM2, PWM3), (PWM4, PWM5) and (PWM6, PWM7) are controlled by PWM2, PWM4 and PWM6 timers and Dead-zone generator 2, 4 and 6, respectively. Refer to Figure 5-33 to Figure 5-40 for the architecture of PWM Timers.

To prevent PWM driving output pin with unsteady waveform, the 16-bit period down counter and 16-bit comparator are implemented with double buffer. When user writes data to counter/comparator buffer registers the updated value will be load into the 16-bit down counter/ comparator at the time down counter reaching zero. The double buffering feature avoids glitch at PWM outputs.

When the 16-bit period down counter reaches zero, the interrupt request is generated. If PWMtimer is set as auto-reload mode, when the down counter reaches zero, it is reloaded with PWM Counter Register (CNRx) automatically then start decreasing, repeatedly. If the PWM-timer is set as one-shot mode, the down counter will stop and generate one interrupt request when it reaches zero.

The value of PWM counter comparator is used for pulse high width modulation. The counter control logic changes the output to high level when down-counter value matches the value of compare register.

The alternate feature of the PWM-timer is digital input Capture function. If Capture function is enabled the PWM output pin is switched as capture input mode. The Capture0 and PWM0 share one timer which is included in PWM0 and the Capture1 and PWM1 share PWM1 timer, and etc. Therefore user must setup the PWM-timer before enable Capture feature. After capture feature is enabled, the capture always latched PWM-counter to Capture Rising Latch Register (CRLR) when input channel has a rising transition and latched PWM-counter to Capture Falling Latch Register (CFLR) when input channel has a falling transition. Capture channel 0 interrupt is programmable by setting CCR0.CRL_IE0[1] (Rising latch Interrupt enable) and CCR0.CFL_IE0[2]] (Falling latch Interrupt enable) to decide the condition of interrupt occur. Capture channel 1 has the same feature by setting CCR0.CRL_IE1[17] and CCR0.CFL_IE1[18]. Capture channel 2 to channel 3 on each group have the same feature by setting the corresponding control bits in CCR2. For each group, whenever Capture issues Interrupt 0/1/2/3, the PWM counter 0/1/2/3 will be reload at this moment.

The maximum captured frequency that PWM can capture is confined by the capture interrupt latency. When capture interrupt occurred, software will do at least three steps, they are: Read PIIR to get interrupt source and Read CRLRx/CFLRx(x=0~3) to get capture value and finally write

1 to clear PIIR to 0. If interrupt latency will take time T0 to finish, the capture signal mustn't transition during this interval (T0). In this case, the maximum capture frequency will be 1/T0. For example:

HCLK = 50 MHz, PWM_CLK = 25 MHz, Interrupt latency is 900 ns

So the maximum capture frequency will is 1/900ns  $\approx 1000$  kHz

### 5.7.2 Features

5.7.2.1 *PWM function features:* 

- PWM group has two PWM generators. Each PWM generator supports one 8-bit prescaler, one clock divider, two PWM-timers (down counter), one dead-zone generator and two PWM outputs.
- Up to 16-bit resolution
- PWM Interrupt request synchronized with PWM period
- One-shot or Auto-reload mode PWM
- Up to 2 PWM group (PWMA/PWMB) to support 8 PWM channels or 4 PWM paired channels

#### 5.7.2.2 Capture Function Features:

- Timing control logic shared with PWM Generators
- Supports 8 Capture input channels shared with 8 PWM output channels
- Each channel supports one rising latch register (CRLR), one falling latch register (CFLR) and Capture interrupt flag (CAPIFx)

### 5.7.3 Block Diagram

The Figure 5-33 to Figure 5-40 illustrate the architecture of PWM in pair (PWM-Timer 0/1 are in one pair and PWM-Timer 2/3 are in another one, and so on.).

### 5.7.4 Functional Description

#### 5.7.4.1 *PWM-Timer Operation*

The PWM period and duty control are configured by PWM down-counter register (CNR) and PWM comparator register (CMR). The PWM-timer timing operation is shown in Figure 5-42. The pulse width modulation follows the formula as below and the legend of PWM-Timer Comparator is shown in Figure 5-41. Note that the corresponding GPIO pins must be configured as PWM function (enable POE and disable CAPENR) for the corresponding PWM channel.

- PWM frequency = PWMxy_CLK/[(prescale+1)*(clock divider)*(CNR+1)]; where xy, could be 01, 23, 45 or 67, depends on selected PWM channel.
- Duty ratio = (CMR+1)/(CNR+1)
- CMR >= CNR: PWM output is always high
- CMR < CNR: PWM low width= (CNR-CMR) unit[1]; PWM high width = (CMR+1) unit
- CMR = 0: PWM low width = (CNR) unit; PWM high width = 1 unit

**Note:** [1] Unit = one PWM clock cycle.

Figure 5-41 Legend of Internal Comparator Output of PWM-Timer

### nuvoTon

Figure 5-42 PWM-Timer Operation Timing

### 5.7.4.2 PWM Double Buffering, Auto-reload and One-shot Operation

PWM Timers have double buffering function the reload value is updated at the start of next period without affecting current timer operation. The PWM counter value can be written into CNRx and current PWM counter value can be read from PDRx.

PWM0 will operate in One-shot mode if CH0MOD bit is set to 0, and operate in Auto-reload mode if CH0MOD bit is set to 1. It is recommend that switch PWM0 operating mode before setting CH0EN bit as 1 to enable PWM0 counter start running because the content of CNR0 and CMR0 will be cleared to 0 to reset the PWM0 period and duty setting when PWM0 operating mode is changed. As PWM0 operate at one-shot mode, CMR0 and CNR0 should be written first and then set CH0EN bit to 1 to enable PWM0 counter to start running. After PWM0 counter down count from CNR0 value to 0, CNR0 and CMR0 will be cleared to 0 by hardware and PWM counter will be held. Software need to write new CMR0 and CNR0 value to set next one-shot period and duty. When re-start next one-shot operation, the CMR0 should be written first because PWM0 counter will auto re-start counting when CNR0 is written an non-zero value. As PWM0 operates in Auto-reload mode, CMR0 and CNR0 should be written first because PWM0 counter will auto re-start running. The value of CNR0 will reload to PWM0 counter when it down count reaches zero. If CNR0 is set to 0, PWM0 counter will be held. PWM1~PWM7 performs the same function as PWM0.

Figure 5-43 PWM Double Buffering Illustration

### nuvoton

#### 5.7.4.3 Modulate Duty Ratio

The double buffering function allows CMRx written at any point in current cycle. The loaded value will take effect from next cycle.

Figure 5-44 PWM Controller Output Duty Ratio

#### 5.7.4.4 Dead-Zone Generator

PWM controller is implemented with Dead Zone generator. They are built for power device protection. This function generates a programmable time gap to delay PWM rising output. User can program PPRx.DZI to determine the Dead Zone interval.

Figure 5-45 Paired-PWM Output with Dead Zone Generation Operation

### 5.7.4.5 Capture Operation

The Capture 0 and PWM 0 share one timer that included in PWM 0; and the Capture 1 and PWM 1 share another timer, and etc. The capture always latches PWM-counter to CRLRx when input channel has a rising transition and latches PWM-counter to CFLRx when input channel has a falling transition. Capture channel 0 interrupt is programmable by setting CCR0[1] (Rising latch Interrupt enable) and CCR0[2] (Falling latch Interrupt enable) to decide the condition of interrupt occur. Capture channel 1 has the same feature by setting CCR0[17] and CCR0[18], and etc. Whenever the Capture controller issues a capture interrupt, the corresponding PWM counter will be reloaded with CNRx at this moment. Note that the corresponding GPIO pins must be configured as capture function (disable POE and enable CAPENR) for the corresponding capture channel.

Figure 5-46 Capture Operation Timing

At this case, the CNR is 8:

- 1. The PWM counter will be reloaded with CNRx when a capture interrupt flag (CAPIFx) is set.
- 2. The channel low pulse width is (CNR + 1 CRLR).
- 3. The channel high pulse width is (CNR + 1 CFLR).

### 5.7.4.6 PWM-Timer Interrupt Architecture

There are eight PWM interrupts, PWM0_INT~PWM7_INT, which are divided into PWMA_INT and PWMB_INT for Advanced Interrupt Controller (AIC). PWM 0 and Capture 0 share one interrupt,

### nuvoTon

PWM1 and Capture 1 share the same interrupt and so on. Therefore, PWM function and Capture function in the same channel cannot be used at the same time. Figure 5-47 and Figure 5-48 demonstrates the architecture of PWM-Timer interrupts.

Figure 5-47 PWM Group A PWM-Timer Interrupt Architecture Diagram

#### Figure 5-48 PWM Group B PWM-Timer Interrupt Architecture Diagram

#### 5.7.4.7 PWM-Timer Start Procedure

The following procedure is recommended for starting a PWM drive.

- 1. Setup clock source divider select register (CSR)
- 2. Setup prescaler (PPR)
- 3. Setup inverter on/off, dead zone generator on/off, auto-reload/one-shot mode and Stop PWM-timer (PCR)
- 4. Setup comparator register (CMR) for setting PWM duty.
- 5. Setup PWM down-counter register (CNR) for setting PWM period.
- 6. Setup interrupt enable register (PIER) (option)
- 7. Setup corresponding GPIO pins as PWM function (enable POE and disable CAPENR) for the corresponding PWM channel.
- 8. Enable PWM timer start running (Set CHxEN = 1 in PCR)

#### 5.7.4.8 PWM-Timer Re-Start Procedure in Single-shot mode

After PWM waveform generated once in PWM one-shot mode, PWM-Timer will stop automatically. The following procedure is recommended for re-starting PWM single-shot waveform.

- 1. Setup comparator register (CMR) for setting PWM duty.
- 2. Setup PWM down-counter register (CNR) for setting PWM period. After setup CNR, PWM wave will be generated.

#### 5.7.4.9 *PWM-Timer Stop Procedure*

#### Method 1:

Set 16-bit down counter (CNR) as 0, and monitor PDR (current value of 16-bit down-counter). When PDR reaches to 0, disable PWM-Timer (CHxEN in PCR). *(Recommended)* 

#### Method 2:

Set 16-bit down counter (CNR) as 0. When interrupt request happened, disable PWM-Timer (CHxEN in PCR). *(Recommended)* 

#### Method 3:

Disable PWM-Timer directly ((CHxEN in PCR). (Not recommended)

The reason why method 3 is not recommended is that disable CHxEN will immediately stop PWM output signal and lead to change the duty of the PWM output, this may cause damage to the control circuit of motor

- 5.7.4.10 Capture Start Procedure
  - 1. Setup clock source divider select register (CSR)
  - 2. Setup prescaler (PPR)
  - 3. Setup channel enabled, rising/falling interrupt enable and input signal inverter on/off (CCR0, CCR2)
  - 4. Setup auto-reload mode, Edge-aligned type and Stop PWM-timer (PCR)
  - 5. Setup PWM down-counter (CNR)
  - 6. Enable PWM timer start running (Set CHxEN = 1 in PCR)
  - 7. Wait until PWM data register (PDR) is not equal to zero to make sure PWM timer is running.
  - 8. Setup corresponding GPIO pins as capture function (disable POE and enable CAPENR) for the corresponding PWM channel.

### 5.8 Real Time Clock (RTC)

#### 5.8.1 Overview

Real Time Clock (RTC) controller provides user the real time and calendar message. The clock source of RTC is from an external 32.768 kHz low speed crystal connected at pins X32I and X32O (Refer to to pin Description) or from an external 32.768 kHz low speed oscillator output fed at pin X32I. The RTC controller provides the time message (second, minute, hour) in Time Loading Register (TLR) as well as calendar message (day, month, year) in Calendar Loading Register (CLR). The data message is expressed in BCD format. It also offers alarm function that user can preset the alarm time in Time Alarm Register (TAR) and alarm calendar in Calendar Alarm Register (CAR).

The RTC controller supports periodic Time Tick and Alarm Match interrupts. The periodic interrupt has 8 period options 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2 and 1 second which are selected by TTR (TTR[2:0]). When RTC counter in TLR and CLR is equal to alarm setting time registers TAR and CAR, the alarm interrupt flag (RIIR.AIF) is set and the alarm interrupt is requested if the alarm interrupt is enabled (RIER.AIER=1). Both RTC Time Tick and Alarm Match can cause chip wake-up from Power-down mode if wake-up function is enabled (TWKE (TTR[3])=1).

#### 5.8.2 Features

- A time counter (second, minute, hour) and calendar counter (day, month, year) for user to check the time
- Alarm register (second, minute, hour, day, month, year)
- 12-hour or 24-hour mode is selectable
- Leap year compensation automatically
- Day of week counter
- Frequency compensate register (FCR)
- All time and calendar message is expressed in BCD code
- Supports periodic time tick interrupt with 8 period options 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2 and 1 second
- Supports RTC Time Tick and Alarm Match interrupt
- Supports wake-up chip from Power-down mode

### 5.8.3 Block Diagram

The block diagram of Real Time Clock is depicted as follows:

Figure 5-49 RTC Block Diagram

### 5.8.4 Functional Description

#### 5.8.4.1 Access to RTC register

Due to clock difference between RTC clock and system clock, when user write new data to any one of the registers, the register will not be updated until 2 RTC clocks later (60us).

In addition, user must be aware that RTC controller does not check whether loaded data is out of bounds or not. RTC does not check rationality between DWR and CLR either.

#### 5.8.4.2 RTC Initiation

When RTC block is powered on, RTC is at reset state. User has to write a number (0xa5eb1357) to INIR to make RTC leaving reset state. Once the INIR is written as 0xa5eb1357, the RTC will be in un-reset state permanently.

#### 5.8.4.3 RTC Read/Write Enable

Register AER bit 15~0 is served as RTC read/write password to protect RTC registers. AER bit 15~0 has to be set as 0xA965 to enable access restriction. Once it is set, it will take effect at least 1024 RTC clocks (about 30ms). Programmer can read RTC enabled status flag in AER.ENF to check whether if RTC controller starts operating or not.

#### 5.8.4.4 Frequency Compensation

The RTC clock source may not precise to exactly 32768 Hz and the RTC register (FCR) allows software to make digital compensation to the RTC source clock if the frequency of RTC source clock is in the range from 32761 Hz to 32776 Hz. Following are the compensation examples for higher or lower frequency clock input.

#### Example 1:

Frequency counter measurement : 32773.65 Hz ( > 32768 Hz)

Integer part: 32773 => 0x8005

FCR.Integer = 0x05 - 0x01 + 0x08 = 0x0c

Fraction part: 0.65 x 60 = 39 => 0x27

FCR.Fraction = 0x27

#### Example 2

Frequency counter measurement : 32765.27 Hz (  $\leq 32768 \text{ Hz}$ ) Integer part:  $32765 \Rightarrow 0x7FFD$ FCR.Integer = 0x0D - 0x01 - 0x08 = 0x04

Fraction part: 0.27 x 60 = 16.2=> 0x10

FCR.Fraction = 0x10

### 5.8.4.5 Time and Calendar counter

TLR and CLR are used to load the time and calendar. TAR and CAR are used for alarm. They are all represented by BCD.

5.8.4.6 12/24 hour Time Scale Selection

The 12/24 hour time scale selection depends on TSSR bit 0.

#### 5.8.4.7 Day of the week counter

The RTC controller provides day of week in Day of the Week Register (DWR). The value is defined from 0 to 6 to represent Sunday to Saturday respectively.

#### 5.8.4.8 *Periodic Time Tick Interrupt*

The periodic interrupt has 8 period option 1/128, 1/64, 1/32, 1/16, 1/8, 1/4, 1/2 and 1 second which are selected by TTR.TTR[2:0]. When periodic time tick interrupt is enabled by setting RIER.TIER to 1, the Periodic Time Tick Interrupt is requested periodically in the period selected by TTR register.

#### 5.8.4.9 Alarm interrupt

When RTC counter in TLR and CLR is equal to alarm setting time TAR and CAR the alarm interrupt flag (RIIR.AIF) is set and the alarm interrupt is requested if the alarm interrupt is enabled (RIER.AIER=1).

#### 5.8.4.10 Application Note:

- 1. TAR, CAR, TLR and CLR registers are all BCD counter.
- 2. Programmer has to make sure that the loaded values are reasonable. For example, Load CLR as 201a (year), 13 (month), 00 (day), or CLR does not match with DWR, etc.

#### 3. Reset state :

Register	Reset State
AER	0
CLR	05/1/1 (year/month/day)
TLR	00:00:00 (hour : minute : second)
CAR	00/00/00 (year/month/day)
TAR	00:00:00 (hour : minute : second)
TSSR	1 (24 hr mode)
DWR	6 (Saturday)
RIER	0
RIIR	0
LIR	0
TTR	0

In CLR and CAR, only 2 BCD digits are used to express "year". We assume 2 BCD digits of xY denote 20xY, but not 19xY or 21xY.

### 5.8.5 Register Map

### 5.9 Serial Peripheral Interface (SPI)

#### 5.9.1 Overview

The Serial Peripheral Interface (SPI) is a synchronous serial data communication protocol which operates in full duplex mode. Devices communicate in master/Slave mode with 4-wire bi-direction interface. The NuMicro[™] NUC130/NUC140 contains up to four sets of SPI controller performing a serial-to-parallel conversion on data received from a peripheral device, and a parallel-to-serial conversion on data transmitted to a peripheral device. Each set of SPI controller can be set as a master, it also can be configured as a slave device controlled by an off-chip master device.

This controller supports a variable serial clock for special application and it also supports 2-bit transfer mode to connect 2 off-chip slave devices at the same time. The SPI controller also supports PDMA function to access the data buffer.

#### 5.9.2 Features

- Up to four sets of SPI controller
- Supports master or Slave mode operation
- Supports 1-bit or 2-bit transfer mode
- Configurable bit length up to 32-bit of a transfer word and configurable word numbers up to 2 of a transaction, so the maximum bit length is 64-bit for each data transfer
- Provides Burst mode operation, transmit/receive can be transferred up to two times word transaction in one transfer
- Supports MSB or LSB first transfer
- Two device/slave select lines in Master mode, but 1 device/slave select line in Slave mode
- Supports byte reorder function
- Supports byte or word suspend mode
- Variable output serial clock frequency in Master mode
- Supports two programmable serial clock frequencies in Master mode
- Supports two channel PDMA request, one for transmitter and another for receiver
- Supports three wire, no slave select signal, bi-direction interface
- SPI clock rate can be configured to equal to the system clock rate

### 5.9.3 Block Diagram

Figure 5-50 SPI Block Diagram

### 5.9.4 Functional Description

#### Master/Slave Mode

This SPI controller can be set as master or Slave mode by setting the SLAVE bit (SPI_CNTRL[18]) to communicate with the off-chip SPI slave or master device. The application block diagrams in Master and Slave mode are shown below.

Figure 5-51 SPI Master Mode Application Block Diagram

Figure 5-52 SPI Slave Mode Application Block Diagram

## nuvoton

#### **Slave Selection**

In Master mode, this SPI controller can drive up to two off-chip slave devices through the slave select output pins SPISSx0 and SPISSx1. In Slave mode, the off-chip master device drives the slave select signal from the SPISSx0 input port to this SPI controller. In master/Slave mode, the active state of slave select signal can be programmed to low active or high active in SS_LVL bit (SPI_SSR[2]), and the SS_LTRIG bit (SPI_SSR[4]) defines the slave select signal SPISSx0/1 is level trigger or edge trigger. The selection of trigger condition depends on what type of peripheral slave/master device is connected.

In Slave mode, if the SS_LTRIG bit is configured as level trigger, the LTRIG_FLAG bit (SPI_SSR[5]) is used to indicate if both the received number and received bits met the requirement which defines in TX_NUM and TX_BIT_LEN among one transaction done (the transaction done means the slave select has deactivated or the SPI controller has finished one data transfer.)

#### Level-trigger / Edge-trigger

In Slave mode, the slave select signal can be configured as level-trigger or edge-trigger. In edgetrigger, the data transfer starts from an active edge and ends on an inactive edge. If master does not send an inactive edge to slave, the transfer procedure will not be completed and the interrupt flag of slave will not be set. In level-trigger, the following two conditions will terminate the transfer procedure and the interrupt flag of slave will be set. The first condition is that if the number of transferred bits matches the settings of TX_NUM and TX_BIT_LEN, the interrupt flag of slave will be set. The second condition, if master set the slave select pin to inactive level during the transfer is in progress, it will force slave device to terminate the current transfer no matter how many bits have been transferred and the interrupt flag will be set. User can read the status of LTRIG_FLAG bit to check if the data has been completely transferred.

### **Automatic Slave Selection**

In Master mode, if the bit AUTOSS (SPI_SSR[3]) is set, the slave select signals will be generated automatically and output to SPISSx0 and SPISSx1 pins depending on whether the SSR[0] (SPI_SSR[0]) and SSR[1] (SPI_SSR[1]) is enabled or not. It means that the slave select signals, which are selected in SSR[1:0], will be asserted by the SPI controller when transmit/receive is started by setting the GO_BUSY bit (SPI_CNTRL[0]) and will be de-asserted after the data transfer is finished. If the AUTOSS bit is cleared, the slave select output signals will be asserted/de-asserted by manual setting/clearing the related bits of SPI_SSR[1:0]. The active state of the slave select output signals is specified in SS_LVL bit (SPI_SSR[2]).

### Serial Clock

In Master mode, set the DIVIDER1 bits (SPI_DIVIDER[15:0]) to program the output frequency of serial clock to the SPICLK output port. It also supports a variable serial clock if the VARCLK_EN bit (SPI_CTL[23]) is enabled. In this case, the output frequency of serial clock can be programmed as one of the two different frequencies which depend on the value of DIVIDER1 (SPI_DIVIDER[15:0]) and DIVIDER2 (SPI_DIVIDER[31:16]). The serial clock rate of each cycle is depended on the setting of the SPI_VARCLK register.

In Slave mode, the off-chip master device drives the serial clock through the SPICLK input port to this SPI controller.

#### Variable Serial Clock Frequency

In Master mode, the output of serial clock can be programmed as variable frequency pattern if the Variable Clock Enable bit VARCLK_EN (SPI_CNTRL[23]) is enabled. The frequency pattern format is defined in VARCLK (SPI_VARCLK[31:0]) register. If the bit content of VARCLK is '0' the output frequency is according with the DIVIDER (SPI_DIVIDER[15:0]) and if the bit content of VARCLK is '1', the output frequency is according to the DIVIDER2 (SPI_DIVIDER[31:16]). Figure 5-53 is the timing relationship among the serial clock (SPICLK), the VARCLK, the DIVIDER and the DIVIDER2 registers. A two-bit combination in the VARCLK defines one clock cycle. The bit field VARCLK[31:30] defines the first clock cycle of SPICLK. The bit field VARCLK[29:28] defines the second clock cycle of SPICLK and so on. The clock source selections are defined in VARCLK and it must be set 1 cycle before the next clock option. For example, if there are 5 CLK1 cycle in SPICLK, the VARCLK shall set 9 '0' in the MSB of VARCLK. The 10th shall be set as '1' in order to switch the next clock source is CLK2. Note that when the VARCLK_EN bit is enabled, the setting of TX_BIT_LEN must be programmed as 0x10 (16-bit mode only).

Figure 5-53 Variable Serial Clock Frequency

### **Clock Polarity**

The CLKP bit (SPI_CTL[11]) defines the serial clock idle state. If CLKP = 1, the output SPICLK is idle at high state, otherwise it is at low state if CLKP = 0.

### **Transmit/Receive Bit Length**

The bit length of a transaction word is defined in TX_BIT_LEN bit field (SPI_CNTRL[7:3]). It can be configured up to 32-bit length in a transaction word for transmitting and receiving.

Figure 5-54 32-Bit in One Transaction

#### **Burst Mode**

SPI controller can switch to Burst mode by setting TX_NUM bit field (SPI_CNTRL[9:8]) to 0x01. In Burst mode, SPI can transmit/receive two transactions in one transfer. The SPI Burst mode waveform is shown below.

Figure 5-55 Two Transactions in One Transfer (Burst Mode)

#### LSB First

The LSB bit (SPI_CNTRL[10]) defines the data transmission either from LSB or MSB firstly to start to transmit/receive data.

### Transmit Edge

The TX_NEG bit (SPI_CNTRL[2]) defines the data transmitted out either at negative edge or at positive edge of serial clock SPICLK.

### **Receive Edge**

The Rx_NEG bit (SPI_CNTRL[1]) defines the data received in either at negative edge or at positive edge of serial clock SPICLK.

**Note:** the settings of TX_NEG and RX_NEG are mutual exclusive. In other words, don't transmit and receive data at the same clock edge.

### Word Suspend

These four bits field of SP_CYCLE (SPI_CNTRL[15:12]) provide a configurable suspend interval  $2 \sim 17$  serial clock periods between two successive transaction words in Master mode. The suspend interval is from the last falling clock edge of the preceding transaction word to the first rising clock edge of the following transaction word if CLKP = 0. If CLKP = 1, the interval is from the rising clock edge of the preceding transaction word to the falling clock edge of the following transaction word to the falling clock edge of the following transaction word to the falling clock edge of the following transaction word to the falling clock edge of the following transaction word. The default value of SP_CYCLE is 0x0 (2 serial clock cycles), but set these bits field has no any effects on data transaction process if TX_NUM = 0x00.

#### **Byte Reorder**

When the transfer is set as MSB first (LSB = 0) and the REORDER is enabled, the data stored in the TX buffer and RX buffer will be rearranged in the order as [BYTE0, BYTE1, BYTE2, BYTE3] in TX_BIT_LEN = 32-bit mode, and the sequence of transmitted/received data will be BYTE0, BYTE1, BYTE2, and then BYTE3. If the TX_BIT_LEN is set as 24-bit mode, the data in TX buffer and RX buffer will be rearranged as [unknown byte, BYTE0, BYTE1, BYTE2]. The SPI controller will transmit/received data with the sequence of BYTE0, BYTE1 and then BYTE2. Each byte will be transmitted/received with MSB first. The rule of 16-bit mode is the same as above. Byte reorder function is only available when TX_BIT_LEN is configured as 16, 24, and 32 bits.

Figure 5-56 Byte Reorder

### **Byte Suspend**

In Master mode, if SPI_CNTRL[19] is set to 1, the hardware will insert a suspend interval 2 ~ 17 serial clock periods between two successive bytes in a transaction word. Both settings of byte suspend and word suspend are configured in SP_CYCLE. Note that when the byte suspend function is enabled, the setting of TX_BIT_LEN must be programmed as 0x00 only (32-bit per transaction word).
### NuMicro™ NUC130/NUC140 Technical Reference Manual

### nuvoTon

Figure 5-57 Timing Waveform for Byte Suspend

REORDER	Description
00	Disable both byte reorder function and byte suspend interval.
01	Enable byte reorder function and insert a byte suspend internal (2~17 SPICLK) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 ( 32 bits/ word)
10	Enable byte reorder function but disable byte suspend function
11	Disable byte reorder function, but insert a suspend interval (2~17 SPICLK) among each byte. The setting of TX_BIT_LEN must be configured as 0x00 ( 32 bits/ word)

Table 5-7 Byte Order and Byte Suspend Conditions

#### No Slave Select Mode (3-WIRE Mode)

This is used to ignore the slave select signal in Slave mode. The SPI controller can work on no slave select mode (3-WIRE mode) interface including SPICLK, SPI_MISO, and SPI_MOSI when it is set as a slave device. When the NOSLVSEL bit is set as 1, the controller will start to transmit/receive data after the GO_BUSY bit is set to 1 and the serial clock appears. In no slave select signal mode, the SS_LTRIG, SPI_SSR[4], shall be set as 1.

#### Interrupt

Each SPI controller can generate an individual interrupt when data transfer is finished and the respective interrupt event flag IF (SPI_CNTRL[16]) will be set. The interrupt event flag will generates an interrupt to CPU if the interrupt enable bit IE (SPI_CNTRL[17]) is set. The interrupt event flag **IF** can be cleared only by writing 1 to it.

In 3-WIRE mode, the interrupt flag in SLV_START_INTSTS will be set when the transfer has start and there is also interrupt event when the received data meet the required bits which define in TX_BIT_LEN and TX_NUM. If the received bits are less than the requirement and there is no more serial clock input over the time period which is defined by the user in Slave mode with no slave select, the user can set the SLV_ABORT bit to force the current transfer done and then the user can get a transfer done interrupt event.

### Two Bit Transfer Mode

This SPI controller also supports two-bit transfer mode when set the TWOB bit (SPI_CNTRL[22]) to 1. When the TWOB bit is enabled, it can transmit and receives two-bit serial data simultaneously.

For example, in Master mode, the data stored at SPI_TX0 register and SPI_TX1 register will be transmitted through the MOSIx0 pin and MOSIx1 pin respectively. In the meanwhile, the SPI_RX0 register and SPI_RX1 register will store the data received from MISOx0 pin and MISOx1 pin respectively.

In Slave mode, the data stored at SPI_TX0 register and SPI_TX1 register will be transmitted through the MISOx0 pin and MISOx1 pin respectively. In the meanwhile, the SPI_RX0 register and SPI_RX1 register will store the data received from MOSIx0 pin and MOSIx1 pin respectively.

Note that when the TWOB bit is enabled, the setting of TX_NUM must be programmed as 0x00 only.

Figure 5-58 Two Bits Transfer Mode (Slave Mode)

### nuvoton

#### 5.9.5 Timing Diagram

The active state of slave select signal can be defined by the settings of SS_LVL bit (SPI_SSR[2]) and SS_LTRIG bit (SPI_SSR[4]). The serial clock (SPICLK) idle state can be configured as high state or low state by setting the CLKP bit (SPI_CNTRL[11]). It also provides the bit length of a transaction word in TX_BIT_LEN (SPI_CNTRL[7:3]), the transfer number in TX_NUM (SPI_CNTRL[8]), and transmit/receive data from MSB or LSB first in LSB bit (SPI_CNTRL[10]). Users also can select which edge of serial clock to transmit/receive data in TX_NEG/RX_NEG (SPI_CNTRL[2:1]) registers. Four SPI timing diagrams for master/slave operations and the related settings are shown below.

### NuMicro™ NUC130/NUC140 Technical Reference Manual

Figure 5-62 SPI Timing in Slave Mode (Alternate Phase of SPICLK)

### 5.9.6 Programming Examples

**Example 1,** SPI controller is set as a master to access an off-chip slave device with following specifications:

- Data bit is latched on positive edge of serial clock
- Data bit is driven on negative edge of serial clock
- Data is transferred from MSB first
- SPICLK is idle at low state
- Only one byte of data to be transmitted/received in a transaction
- Use the first SPI slave select pin to connect with an off-chip slave device. Slave select signal is active low

The operation flow is as follows:

- 1) Set the DIVIDER (SPI_DIVIDER [15:0]) register to determine the output frequency of serial clock.
- 2) Write the SPI_SSR register a proper value for the related settings of Master mode
  - 1. Disable the <u>Automatic Slave Select</u> bit AUTOSS(SPI_SSR[3] = 0)
    - Select low level trigger output of slave select signal in the <u>Slave Select Active Level</u> bit SS_LVL (SPI_SSR[2] = 0)
  - 2. Select slave select signal to be output active at the I/O pin by setting the <u>Slave Select</u> <u>Register</u> bits SSR[0] (SPI_SSR[0]) to active the off-chip slave devices
- 3) Write the related settings into the SPI_CNTRL register to control this SPI master actions
  - 1. Set this SPI controller as master device in SLAVE bit (SPI_CNTRL[18] = 0)
  - 2. Force the serial clock idle state at low in CLKP bit (SPI_CNTRL[11] = 0)

- Select data transmitted at negative edge of serial clock in TX_NEG bit (SPI_CNTRL[2] = 1)
- 4. Select data latched at positive edge of serial clock in RX_NEG bit (SPI_CNTRL[1] = 0)
- 5. Set the bit length of word transfer as 8-bit in TX_BIT_LEN bit field (SPI_CNTRL[7:3] = 0x08)
- 6. Set only one time of word transfer in TX_NUM (SPI_CNTRL[9:8] = 0x0)
- 7. Set MSB transfer first in MSB bit (SPI_CNTRL[10] = 0), and don't care the SP_CYCLE bit field (SPI_CNTRL[15:12]) due to it's not in Burst mode in this case
- 4) If this SPI master will transmits (writes) one byte data to the off-chip slave device, write the byte data that will be transmitted into the TX0[7:0] (SPI_TX0[7:0]) register.
- 5) If this SPI master just only receives (reads) one byte data from the off-chip slave device, you don't need to care what data will be transmitted and just write 0xFF into the SPI_TX0[7:0] register.
- 6) Enable the GO_BUSY bit (SPI_CNTRL [0] = 1) to start the data transfer at the SPI interface.
- 7) Waiting for SPI interrupt occurred (if the Interrupt Enable IE bit is set) or just polling the GO_BUSY bit till it is cleared to 0 by hardware automatically.
- 8) Read out the received one byte data from RX0 [7:0] (SPI_RX0[7:0]) register.
- 9) Go to 4) to continue another data transfer or set SSR [0] to 0 to inactivate the off-chip slave devices.

**Example 2**, The SPI controller is set as a slave device and connects with an off-chip master device. The off-chip master device communicates with the on-chip SPI slave controller through the SPI interface with the following specifications:

- Data bit is latched on positive edge of serial clock
- Data bit is driven on negative edge of serial clock
- Data is transferred from LSB first
- SPICLK is idle at high state
- Only one byte of data to be transmitted/received in a transaction
- Slave select signal is high level trigger

The operation flow is as follows:

1) Write the SPI_SSR register a proper value for the related settings of Slave mode

Select high level and level trigger for the input of slave select signal by setting the Slave Select Active Level bit  $SS_LVL$  (SPI_SSR[2] = 1) and the Slave Select Level Trigger bit  $SS_LTRIG$  (SPI_SSR[4] = 1).

- 2) Write the related settings into the SPI_CNTRL register to control this SPI slave actions
  - 1. Set this SPI controller as slave device in SLAVE bit (SPI_CNTRL[18] = 1)
  - 2. Select the serial clock idle state at high in CLKP bit (SPI_CNTRL[11] = 1)
  - Select data transmitted at negative edge of serial clock in TX_NEG bit (SPI_CNTRL[2] = 1)

- Select data latched at positive edge of serial clock in RX_NEG bit (SPI_CNTRL[1] = 0) 4.
- Set the bit length of word transfer as 8-bit in TX BIT LEN bit field (SPI CNTRL[7:3] = 5. 0x08)
- Set only one time of word transfer in TX_NUM (SPI_CNTRL[9:8] = 0x0) 6.
- Set LSB transfer first in LSB bit (SPI_CNTRL[10] = 1), and don't care the SP_CYCLE bit 7. field (SPI_CNTRL[15:12]) due to not Burst mode in this case.
- 3) If this SPI slave will transmits (be read) one byte data to the off-chip master device, write the byte data that will be transmitted into the TX0 [7:0] (SPI_TX0[7:0]) register.
- 4) If this SPI slave just only receives (be written) one byte data from the off-chip master device, you don't care what data will be transmitted and just write 0xFF into the SPI_TX0[7:0] register.
- 5) Enable the GO_BUSY bit (SPI_CNTRL[0] = 1) to wait for the slave select trigger input and serial clock input from the off-chip master device to start the data transfer at the SPI interface.
- 6) Waiting for SPI interrupt occurred (if the Interrupt Enable IE bit is set), or just polling the GO BUSY bit till it is cleared to 0 by hardware automatically.
- 7) Read out the received one byte data from RX[7:0] (SPI_RX0[7:0]) register.

Go to 3) to continue another data transfer or disable the GO BUSY bit to stop data transfer.

	SP_C	YCLE		CLKP	LSB	TX_NUM		
7	6	5	4	3	2	1	0	
		TX_BIT_LEN			TX_NEG	RX_NEG	GO_BUSY	

Bits	Description	
[31:24]	Reserved	Reserved
		Variable Clock Enable (Master Only)
		1 = The serial clock output frequency is variable. The output frequency is decided by the value of VARCLK, DIVIDER, and DIVIDER2.
[23]	VARCLK_EN	0 = The serial clock output frequency is fixed and decided only by the value of DIVIDER.
		<b>Note:</b> When this VARCLK_EN bit is enabled, the setting of TX_BIT_LEN must be programmed as 0x10 (16-bit mode)
		Two Bits Transfer Mode Active
S		1 = Two-bit transfer mode Enabled.
[22]	туов	0 = Two-bit transfer mode Disabled.
	365	<b>Note1:</b> When TWOB is enabled, the serial transmitted 2-bit data output are from SPI_TX1/0, and the received 2-bit data input are put in SPI_RX1/0.
Yes	40	Note2: When TWOB is enabled, the setting of TX_NUM must be programmed as 0x00
[21]	Reserved	Reserved
	50 00	Reorder Mode Selection
	XSA B	00 = Both byte reorder and byte suspend functions Disabled.
[20:19]	REORDER	01 = Byte reorder function Enabled and a byte suspend interval (2~17 SPICLK cycles) inserted among each byte. The setting of TX_BIT_LEN must be configured as 0x00. (32 bits/word)
	622	10 = Byte reorder function Enabled, but byte suspend function Disabled.
	5	11 = byte reorder function Disabled, but a suspend interval (2~17 SPICLK cycles)

		inserted among each byte. The setting of TX_BIT_LEN must be configured as 0x00. (32 bits/word)
		Note:
		<ol> <li>Byte reorder function is only available if TX_BIT_LEN is defined as 16, 24, and 32 bits.</li> </ol>
		<ol> <li>In Slave mode with level-trigger configuration, if the byte suspend function is enabled, the slave select pin must be kept at active state during the successive four bytes transfer.</li> </ol>
		Slave Mode Enable Bit
[18]	SLAVE	1 = Slave mode
		0 = Master mode
		Interrupt Enable
[17]	IE	1 = SPI Interrupt Enabled
		0 = SPI Interrupt Disabled
		Interrupt Flag
		1 = Transfer is done.
[16]	IF	0 = Transfer is not finished yet.
		Note: This bit will be cleared by writing 1 to itself.
		Suspend Interval (Master Only)
		These four bits provide configurable suspend interval between two successive transmit/receive transaction in a transfer. The suspend interval is from the last falling clock edge of the current transaction to the first rising clock edge of the successive transaction if CLKP = 0. If CLKP = 1, the interval is from the rising clock edge to the falling clock edge. The default value is 0x0. When TX_NUM = 00b, setting this field ha no effect on transfer. The desired suspend interval is obtained according to the following equation:
		For byte suspend interval and Burst mode suspend interval:
		(SP_CYCLE[3:0] + 2) * period of SPICLK + 1 system clock cycle
[15:12]	SP_CYCLE	Ex:
[13.12]	SF_CICLE	SP_CYCLE = 0x0 2 SPICLK clock cycle + 1 system clock cycle
		SP_CYCLE = 0x1 3 SPICLK clock cycle + 1 system clock cycle
S		
		SP_CYCLE = 0xE 16 SPICLK clock cycle + 1 system clock cycle
A.		SP_CYCLE = 0xF 17 SPICLK clock cycle + 1 system clock cycle
		If the SPI clock rate equals system clock rate, that is to say, the DIV_ONE feature is enabled, the Burst mode suspend interval period is
SS		(SP_CYCLE[3:0] * 2 + 3.5) * period of system clock
0	500	Clock Polarity
[11]	CLKP	1 = SPICLK idle high
	Va G	0 = SPICLK idle low
	52	LSB First
[10]	LSB	1 = LSB is sent first on the line (bit 0 of SPI_TX0/1), and the first bit received from the line will be put in the LSB position in the RX register (bit 0 of SPI_RX0/1).
	1	0 = MSB is transmitted/received first (which bit in SPI_TX0/1 and SPI_RX0/1 register

		that is depends on the TX_BIT_LEN field).
		Numbers of Transmit/Receive Word
		This field specifies how many transmit/receive word numbers should be executed in one transfer.
		00 = Only one transmit/receive word will be executed in one transfer.
[9:8]	TX_NUM	01 = Two successive transmit/receive words will be executed in one transfer. (Burst mode)
		10 = Reserved.
		11 = Reserved.
		<b>Note:</b> in Slave mode with level-trigger configuration, if TX_NUM is set to 01, the slave select pin must be kept at active state during the successive data transfer.
		Transmit Bit Length
		This field specifies how many bits can be transmitted / received in one transaction. The minimum bit length is 8 bits and can up to 32 bits.
[7:3]	TX_BIT_LEN	TX_BIT_LEN = 0x08 8 bits
		TX_BIT_LEN = 0x1F 31 bits
		TX_BIT_LEN = 0x00 32 bits
		Transmit At Negative Edge
[2]	TX_NEG	1 = The transmitted data output signal is changed at the falling edge of SPICLK
		0 = The transmitted data output signal is changed at the rising edge of SPICLK
		Receive At Negative Edge
[1]	RX_NEG	1 = The received data input signal is latched at the falling edge of SPICLK
		0 = The received data input signal is latched at the rising edge of SPICLK
		Go and Busy Status
		<ul><li>1 = In Master mode, writing 1 to this bit to start the SPI data transfer; in Slave mode, writing 1 to this bit indicates that the slave is ready to communicate with a master.</li></ul>
[0]	GO_BUSY	0 = Stop data transfer if SPI is transferring.
		During the data transfer, this bit keeps the value of 1. As the transfer is finished, this bit will be cleared automatically.
		Note: All registers should be set before writing 1 to this GO_BUSY bit.

### SPI Divider Register (SPI_DIVIDER)

Register	Offset	R/W	Description	Reset Value
SPI_DIVIDER n=0,13		R/W	Clock Divider Register (Master Only)	0x0000_0000

				1 S S 32 3			
31	30	29	28	27	26	25	24
			DIVIDEI	R2[15:8]	B S	2	
23	22	21	20	19	18	17	16
			DIVIDE	R2[7:0]		200	
15	14	13	12	11	10	9	8
			DIVIDE	R[15:8]		100	6
7	6	5	4	3	2	1	0
			DIVIDE	ER[7:0]		Z	2016

Bits	Description	
		Clock Divider 2 (Master Only)
		The value in this field is the 2 nd frequency divider for generating the serial clock on the output SPICLK. The desired frequency is obtained according to the following equation:
[31:16]	DIVIDER2	$f_{sclk} = \frac{f_{pclk}}{(DIVIDER2 + 1) * 2}$ If VARCLK EN is cleared to 0, this setting is unmeaning.
		Clock Divider 1 (master only)
		The value in this field is the frequency divider for generating the serial clock on the output SPICLK. The desired frequency is obtained according to the following equation:
[15:0]	DIVIDER	$f_{sclk} = \frac{f_{pclk}}{(DIVIDER+1)*2}$
Ny z		In Slave mode, the period of SPI clock driven by a master shall equal or over 5 times the period of PCLK. In other words, the maximum frequency of SPI clock is the fifth of the frequency of slave's PCLK.

### SPI Slave Select Register (SPI_SSR)

Register	Offset	R/W	Description	Reset Value
SPI_SSR		R/W	Clove Select Degister	0,0000,0000

			Rese	erved		100	6
7	6	5	4	3	2	1	0
Reserved		LTRIG_FLAG	SS_LTRIG	AUTOSS	SS_LVL	S	SR
							20.1

	Bits	Description					
	[31:6]	Reserved	Reserved				
			Level Trigger Accomplish Flag				
			When the SS_LTRIG bit is set in Slave mode, this bit can be read to indicate the received bit number is met the requirement or not.				
	[5]	LTRIG_FLAG	1 = The transaction number and the transferred bit length met the specified requirements which defined in TX_NUM and TX_BIT_LEN.				
			0 = The transaction number or the transferred bit length of one transaction doesn't meet the specified requirements.				
			Note: This bit is READ only				
			Slave Select Level Trigger Enable Bit (Slave Only)				
	[4]	SS_LTRIG	1 = The slave select signal will be level-trigger. It depends on SS_LVL to decide the signal is active low or active high.				
	20		0 = The input slave select signal is edge-trigger. This is the default value. It depends on SS_LVL to decide the signal is active at falling-edge or rising-edge				
	X		Automatic Slave Select Enable Bit (Master only)				
	[3]	AUTOSS	1 = If this bit is set, SPISSx0/1 signals will be generated automatically. It means that device/slave select signal, which is set in SSR[1:0], will be asserted by the SPI controller when transmit/receive is started by setting GO_BUSY, and will be de-asserted after each transmit/receive is finished.				
	Ŷ	D'C	0 = If this bit is cleared, slave select signals will be asserted/de-asserted by setting /clearing related bits in SSR[1:0].				
		~ (D) (P)	Slave Select Active Level				
	[0]	SS 1.14	It defines the active status of slave select signal (SPISSx0/1).				
	[2]	SS_LVL	1 = The slave select signal SPISSx0/1 is active at high-level/rising-edge.				
		~	0 = The slave select signal SPISSx0/1 is active at low-level/falling-edge.				

		Slave Select Control Bits (Master Only)
		If AUTOSS bit is cleared, writing 1 to any bit location of this field sets the proper SPISSx0/1 line to an active state and writing 0 sets the line back to inactive state.
[1:0]	SSR	If AUTOSS bit is set, writing 0 to any bit location of this field will keep the corresponding SPISSx0/1 line at inactive state; writing 1 to any bit location of this field will select the corresponding SPISSx0/1 line to be automatically driven to active state for the duration of the transmit/receive, and will be driven to inactive state for the rest of the time. The active state of SPISSx0/1 is specified in SS_LVL.
		Note: SPISSx0 is also defined as slave select input in Slave mode.

### SPI Data Receive Register (SPI_RX)

Register	Offset	R/W	Description	Reset Value
SPI_RX0 n=0,13	SPIn_BA+0x10	R	Data Receive Register 0	0x0000_0000

7	6	5	4	3	2	1	0
			Reserved				DIV_ONE

	Bits	Description	Description				
	[31:12]	Reserved	Reserved				
			Slave 3-Wire Mode Start Interrupt Status				
	[11]	SLV_START_INTSTS	It is used to dedicate that the transfer has start in Slave mode with no slave select.				
	[11]	SLV_START_INTSTS	1 = It indicates that the transfer start in Slave mode with no slave select. It is auto clear by transfer done or writing one clear.				
			0 = It indicates that the slave start transfer no active.				
			Slave 3-Wire Mode Start Interrupt Enable				
	[10]	SSTA_INTEN	It is used to enable interrupt when the transfer has start in Slave mode with no slave select. If there is no transfer done interrupt over the time period which is defined by user after the transfer start, the user can set the SLV_ABORT bit to force the transfer done.				
			1 = Transaction start interrupt Enabled. It is clear by the current transfer done or the SLV_START_INTSTS bit be clear (write one clear).				
	62.20	15	0 = Transfer start interrupt Disabled.				
	223	6	Slave 3-Wire Mode Abort Control Bit				
	° Q	b Cr.	In normal operation, there is interrupt event when the received data meet the required bits which define in TX_BIT_LEN and TX_NUM.				
	[9]	SLV_ABORT	If the received bits are less than the requirement and there is no more serial clock input over the one transfer time in Slave mode with no slave select, the user can set this bit to force the current transfer done and then the user can get a transfer done interrupt event.				
		193.12	Note: It is auto cleared to 0 by hardware when the abort event is active.				
	[8]	NOSLVSEL	Slave 3-Wire Mode Enable Bit				
^	Lug 22 2013	122	Page 307 of 573 Revision V2 05				

		<ul> <li>when it is set as a slave device.</li> <li>0 = The controller is 4-wire bi-direction interface.</li> <li>1 = The controller is 3-wire bi-direction interface in Slave mode. When this bit is</li> </ul>
		set as 1, the controller start to transmit/receive data after the GO_BUSY bit active and the serial clock input.
		<b>Note:</b> In no slave select signal mode, the SS_LTRIG, SPI_SSR[4], shall be set as 1.
[7:1]	Reserved	Reserved
		SPI Clock Divider Control
		0 = The SPI clock rate is determined by the setting of SPI_DIVIDER register.
		1 = DIV_ONE feature Enabled. The SPI clock rate equals the system clock rate.
[0]	DIV_ONE	Note:
		<ol> <li>When this bit is set as 1, both the REORDER field and the VARCLK_EN field must be configured as 0. In other words, the byte-reorder function, byte suspend function and variable clock function must be disabled.</li> </ol>
		2. When this bit is set as 1, the TX_BIT_LEN cannot be set as 1.

### 5.10 Timer Controller (TMR)

#### 5.10.1 Overview

The timer controller includes four 32-bit timers, TIMER0~TIMER3, which allows user to easily implement a timer control for applications. The timer can perform functions like frequency measurement, event counting, interval measurement, clock generation, delay timing, and so on. The timer can generate an interrupt signal upon timeout, or provide the current value during operation.

#### 5.10.2 Features

- 4 sets of 32-bit timers with 24-bit up-timer and one 8-bit pre-scale counter
- Independent clock source for each timer
- Provides one-shot, periodic, toggle and continuous counting operation modes
- Time out period = (Period of timer clock input) * (8-bit pre-scale counter + 1) * (24-bit TCMP)
- Maximum counting cycle time = (1 / T MHz) * (2⁸) * (2²⁴), where T is the period of timer clock
- 24-bit timer value is readable through TDR (Timer Data Register)
- Supports event counting function to count the event from external pin
- Supports input capture function to capture or reset counter value

### 5.10.3 Block Diagram

Each channel is equipped with an 8-bit pre-scale counter, a 24-bit up-timer, a 24-bit compare register and an interrupt request signal. Refer to Figure 5-63 for the timer controller block diagram. There are four options of clock sources for each channel. Figure 5-64 illustrates the clock source control function. Software can program the 8-bit pre-scale counter to decide the clock period to 24-bit up timer.

#### 5.10.4 Functional Description

Timer controller provides One-shot, Period, Toggle and Continuous Counting Operation modes. It also provides the event counting function to count the event from external pin and input capture function to capture or reset timer counter value. Each operating function mode is shown as follows:

#### 5.10.4.1 One-shot Mode

If timer is operated in One-shot mode and CEN (TCSR[30] timer enable bit) is set to 1, the timer counter starts up counting. Once the timer counter value reaches timer compare register (TCMPR) value, if IE (TCSR[29] interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU. It indicates that the timer counting overflow happens. If IE (TCSR[29] interrupt enable bit) is set to 0, no interrupt signal is generated. In this operating mode, once the timer counter value reaches timer compare register (TCMPR) value, the timer counter value goes back to counting initial value and CEN (timer enable bit) is cleared to 0 by timer controller. Timer counting operation stops, once the timer counter value reaches timer operates timer counter value function only one time after programming the timer compare register (TCMPR) value and CEN (timer enable bit) is set to 1. So, this operating mode is called One-Shot mode.

#### 5.10.4.2 Periodic Mode

If timer is operated in Period mode and CEN (TCSR[30] timer enable bit) is set to 1, the timer counter starts up counting. Once the timer counter value reaches timer compare register (TCMPR) value, if IE (TCSR[29] interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU. It indicates that the timer counting overflow happens. If IE (TCSR[29] interrupt enable bit) is set to 0, no interrupt signal is generated. In this operating mode, once the timer counter value reaches timer compare register (TCMPR) value, the timer counter value goes back to counting initial value and CEN is kept at 1 (counting enable continuously). The timer counter operates up counting again. If the interrupt flag is cleared by software, once the timer counter value reaches timer compare register (TCMPR) value and IE (interrupt enable bit) is set to 1'b1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU again. That is to say, timer operates timer counting and compares with TCMPR value function periodically. The timer counting operation does not stop until the CEN is set to 0. The interrupt signal is also generated periodically. So, this operating mode is called Periodic mode.

#### 5.10.4.3 Toggle Mode

If timer is operated in Toggle mode and CEN (TCSR[30] timer enable bit) is set to 1, the timer counter starts up counting. Once the timer counter value reaches timer compare register (TCMPR) value, if IE (TCSR[29] interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU. It indicates that the timer counting overflow happens. The associated toggle output (tout) signal is set to 1. In this operating mode, once the timer counter value reaches timer compare register (TCMPR) value, the timer counter value goes back to counting initial value and CEN is kept at 1 (counting enable continuously). The timer counter operates up counting again. If the interrupt flag is cleared by software, once the timer counter value reaches timer compare register (TCMPR) value and IE (interrupt enable bit) is set to 1, then the timer interrupt flag is set and the interrupt signal is generated and sent to NVIC to inform CPU again. The associated toggle output (tout) signal is set to 0. The timer counting operation does not stop until the CEN is set to 0. Thus, the toggle output (tout) signal is called Toggle mode.

#### 5.10.4.4 Continuous Counting Mode

If the timer is operated in Continuous Counting mode and CEN (TCSR[30] timer enable bit) is set to 1, the associated interrupt signal is generated depending on TDR = TCMPR if IE (TCSR[29] interrupt enable bit) is enabled. User can change different TCMPR value immediately without disabling timer counting and restarting timer counting. For example, TCMPR is set as 80, first. (The TCMPR should be less than  $2^{24}$  and be greater than 1). The timer generates the interrupt if IE is enabled and TIF (timer interrupt flag) will set to 1 then the interrupt signal is generated and sent to NVIC to inform CPU when TDR value is equal to 80. But the CEN is kept at 1 (counting enable continuously) and TDR value will not goes back to 0, it continues to count 81, 82, 83,^{...} to  $2^{24}$  -1, 0, 1, 2, 3, ^{...} to  $2^{24}$  -1 again and again. Next, if user programs TCMPR as 200 and the TIF is cleared to 0, then timer interrupt occurred and TIF is set to 1, then the interrupt signal is generated and sent to NVIC to inform CPU again when TDR value reaches to 200. At last, user programs TCMPR as 500 and clears TIF to 0 again, then timer interrupt occurred and TIF sets to 1 then the interrupt signal is generated and sent to NVIC to inform CPU when TDR value reaches to 500. From application view, the interrupt is generated depending on TCMPR. In this mode, the timer counting is continuous. Thus, this operation mode is called Continuous Counting mode.

Figure 5-65 Continuous Counting Mode

### 5.10.4.5 Event Counting Function

An application which can count the event from TM0~TM3 pins is provided. It is called as event counting function. In event counting function, the clock source of timer controller, TMRx_CLK, in Figure 5-65 should be set as HCLK. It provides TM0~TM3 enabled or disabled de-bounce function by TEXCONx[7] and TM0~TM3 falling or rising phase counting setting by TEXCONx[0]. Also, the event count source operating frequency should be less than 1/3 HCLK frequency if counting de-bounce is disabled or less than 1/8 HCLK frequency if counting de-bounce is enabled. Otherwise, the returned TDR value is incorrect.

### nuvoton

#### 5.10.4.6 Input Capture Function

The input capture function is also provided to capture or reset timer counter value. If TEXEN (Timer External Pin Enable) is set to 1 and RSTCAPSEL is set to 0, the timer counter value (TDR) will be captured into TCAP register when TEX (Timer External Pin) pin trigger condition occurred. There are four TEX sources form specified pins, T0EX~T3EX pins. If TEXEN is set to 1 and RSTCAPSEL is set to 1, the TDR will be reset to 0 when TEX pin trigger condition happened. The TEX trigger edge can choose by TEX_EDGE. When TEX trigger occurred, TEXIF (Timer External Interrupt Flag) is set to 1, and if enabled TEXIEN (Timer External Interrupt Enable Bit) to 1, the interrupt signal is generated then sent to NVIC to inform CPU. It also provides T0EX~T3EX enabled or disabled capture de-bounce function by TEXCONx[6]. Also, the TEX source operating frequency should be less than 1/3 HCLK frequency if TEX de-bounce is disabled or less than 1/8 HCLK frequency if TEX de-bounce is enabled.

Timer Compared Value         TCMP         TCMP	Bits	Description	
TCMP       TCMP is a 24-bit compared register. When the internal 24-bit up-timer counts and its value is equal to TCMP value, a Timer Interrupt is requested if the timer interrupt is enabled with TCSR.IE[29]=1. The TCMP value defines the timer counting cycle time.         TCMP       Time out period = (Period of timer clock input) * (8-bit PRESCALE + 1) * (24-bit TCMP Note1: Never write 0x0 or 0x1 in TCMP, or the core will run into unknown state.         Note2: When timer is operating in Continuous Counting mode, the 24-bit up-timer will count continuously if software writes a new value into TCMP. If timer is operating at	[31:24]	Reserved	Reserved

	[0]	TEXIF	This bit is set by hardware when TEXEN (TEXCON[3]) is to 1, and the transition on the TEX pins associated with TEX_EDGE (TEXCON[2:1]) setting is occurred. It is cleared by writing 1 to this bit.				
The second			For example, while TEXEN = 1, and TEX_EDGE = 00, a 1 to 0 transition on the TEX pin causes the TEXIF to be set.				
### nuvoton

#### 5.11 Watchdog Timer (WDT)

#### 5.11.1 Overview

The purpose of Watchdog Timer is to perform a system reset when system runs into an unknown state. This prevents system from hanging for an infinite period of time. Besides, this Watchdog Timer supports another function to wake-up chip from Power-down mode. The watchdog timer includes an 18-bit free running counter with programmable time-out intervals. Table 5-8 show the watchdog timeout interval selection and Figure 5-64 shows the timing of watchdog interrupt signal and reset signal.

Setting WTE (WDTCR [7]) enables the watchdog timer and the WDT counter starts counting up. When the counter reaches the selected time-out interval, Watchdog timer interrupt flag WTIF will be set immediately to request a WDT interrupt if the watchdog timer interrupt enable bit WTIE is set, in the meanwhile, a specified delay time (1024 * T_{WDT}) follows the time-out event. User must set WTR (WDTCR [0]) (Watchdog timer reset) high to reset the 18-bit WDT counter to avoid chip from Watchdog timer reset before the delay time expires. WTR bit is cleared automatically by hardware after WDT counter is reset. There are eight time-out intervals with specific delay time which are selected by Watchdog timer interval select bits WTIS (WDTCR [10:8]). If the WDT counter has not been cleared after the specific delay time expires, the watchdog timer will set Watchdog Timer Reset Flag (WTRF) high and reset chip. This reset will last 63 WDT clocks (T_{RST}) then chip restarts executing program from reset vector (0x0000 0000). WTRF will not be cleared by Watchdog reset. User may poll WTRF by software to recognize the reset source. WDT also provides wake-up function. When chip is powered down and the Watchdog Timer Wake-up Function Enable bit (WDTR[4]) is set, if the WDT counter reaches the specific time interval defined by WTIS (WDTCR [10:8]), the chip is woken up from Power-down state. As to the fist example, if WTIS is set as 000, the specific time interval for chip to wake up from Power-down state is  $2^4 * T_{WDT}$ . When power down command is set by software, then, chip enters Power-down state. After  $2^4 * T_{WDT}$  time is elapsed, chip is woken up from Power-down state. As to the second example, if WTIS (WDTCR [10:8]) is set as 111, the specific time interval for chip to wake up from Power-down state is  $2^{18} * T_{WDT}$ . If power down command is set by software, then, chip enters Power-down state. After  $2^{18} * T_{WDT}$  time is elapsed, chip is woken up from Power-down state. Note that if WTRE (WDTCR [1]) is set to 1, after chip is woken up, software should clear the Watchdog Timer counter by setting WTR(WDTCR [0]) to 1 as soon as possible. Otherwise, if the Watchdog Timer counter is not cleared by setting WTR (WDTCR [0]) to 1 before time starting from waking A CONCERNING OF THE REAL OF TH up to software clearing Watchdog Timer counter is over 1024 * T_{WDT}, the chip is reset by

WTIS	Timeout Interval Selection T _{TIS}	Interrupt Period T _{INT}	WTR Timeout startingInterval (WDT_CLK=10 kHz) MIN. T _{WTR} ~ Max. T _{WTR}

### nuvoton

#### 5.12 UART Interface Controller (UART)

The NuMicro[™] NUC130/NUC140 provides up to three channels of Universal Asynchronous Receiver/Transmitters (UART). UART0 supports High Speed UART and UART1~2 perform Normal Speed UART, besides, only UART0 and UART1 support flow control function.

#### 5.12.1 Overview

The Universal Asynchronous Receiver/Transmitter (UART) performs a serial-to-parallel conversion on data received from the peripheral, and a parallel-to-serial conversion on data transmitted from the CPU. The UART controller also supports IrDA SIR Function, LIN Master/Slave mode function and RS-485 mode functions. Each UART channel supports seven types of interrupts including transmitter FIFO empty interrupt (INT THRE), receiver threshold level reaching interrupt (INT_RDA), line status interrupt (parity error or framing error or break interrupt) (INT_RLS), receiver buffer time out interrupt (INT_TOUT), MODEM/Wake-up status interrupt (INT MODEM), Buffer error interrupt (INT BUF ERR) and LIN receiver break field detected interrupt (INT LIN RX BREAK). Interrupts of UART0 and UART2 share the interrupt number 12 (vector number is 28); Interrupt number 13 (vector number is 29) only supports UART1 interrupt. Refer to Nested Vectored Interrupt Controller chapter for System Interrupt Map.

The UART0 is built-in with a 64-byte transmitter FIFO (TX FIFO) and a 64-byte receiver FIFO (RX FIFO) that reduces the number of interrupts presented to the CPU and the UART1~2 are equipped 16-byte transmitter FIFO (TX_FIFO) and 16-byte receiver FIFO (RX_FIFO). The CPU can read the status of the UART at any time during the operation. The reported status information includes the type and condition of the transfer operations being performed by the UART, as well as 4 error conditions (parity error, framing error, break interrupt and buffer error) probably occur while receiving data. The UART includes a programmable baud rate generator that is capable of dividing clock input by divisors to produce the serial clock that transmitter and receiver need. The baud rate equation is Baud Rate = UART_CLK / M * [BRD + 2], where M and BRD are defined in Baud Rate Divider Register (UA BAUD). Table 5-9 lists the equations in the various conditions and Table 5-10 list the UART baud rate setting table.

Mode	DIV_X_EN	DIV_X_ONE	Divider X	BRD	Baud rate Equation				
0	0	0	В	А	UART_CLK / [16 * (A+2)]				
1	1	0	В	А	UART_CLK / [(B+1) * (A+2)] , B must >= 8

Table 5-10 UART Baud Rate Setting Table

The UART0 and UART1 controllers support auto-flow control function that uses two low-level signals, /CTS (clear-to-send) and /RTS (request-to-send), to control the flow of data transfer between the UART and external devices (ex: Modem). When auto-flow is enabled, the UART is not allowed to receive data until the UART asserts /RTS to external device. When the number of bytes in the RX FIFO equals the value of RTS_TRI_LEV (UA_FCR [19:16]), the /RTS is deasserted. The UART sends data out when UART controller detects /CTS is asserted from external device. If a valid asserted /CTS is not detected the UART controller will not send data out.

The UART controllers also provides Serial IrDA (SIR, Serial Infrared) function (User must set IrDA_EN (UA_FUN_SEL [1]) to enable IrDA function). The SIR specification defines a short-range infrared asynchronous serial transmission mode with one start bit, 8 data bits, and 1 stop bit. The maximum data rate is 115.2 Kbps (half duplex). The IrDA SIR block contains an IrDA SIR Protocol encoder/decoder. The IrDA SIR protocol is half-duplex only. So it cannot transmit and receive data at the same time. The IrDA SIR physical layer specifies a minimum 10ms transfer delay between transmission and reception. This delay feature must be implemented by software.

The alternate function of UART controllers is LIN (Local Interconnect Network) function. The LIN mode is selected by setting the UA_FUN_SEL[1:0] to '01'. In LIN mode, one start bit and 8-bit data format with 1-bit stop bit are required in accordance with the LIN standard.

For NuMicro[™] NUC100 Series, another alternate function of UART controllers is RS-485 9-bit mode function, and direction control provided by RTS pin or can program GPIO (PB.2 for RTS0 and PB.6 for RTS1) to implement the function by software. The RS-485 mode is selected by setting the UA_FUN_SEL register to select RS-485 function. The RS-485 driver control is implemented using the RTS control signal from an asynchronous serial port to enable the RS-485 driver. In RS-485 mode, many characteristics of the RX and TX are same as UART.

#### 5.12.2 Features

- Full duplex, asynchronous communications
- Separates receive/transmit 64/16/16 bytes (UART0/UART1/UART2) entry FIFO for data payloads
- Supports hardware auto flow control/flow control function (CTS, RTS) and programmable RTS flow control trigger level (UART0 and UART1 support)
- Programmable receiver buffer trigger level
- Supports programmable baud-rate generator for each channel individually
- Supports CTS wake-up function (UART0 and UART1 support)
- Supports 7-bit receiver buffer time out detection function
- UART0/UART1 can be served by the DMA controller
- Programmable transmitting data delay time between the last stop and the next start bit by setting UA_TOR [DLY] register
- Supports break error, frame error, parity error and receive / transmit buffer overflow detect function
- Fully programmable serial-interface characteristics
  - Programmable number of data bit, 5-, 6-, 7-, 8-bit character
  - Programmable parity bit, even, odd, no parity or stick parity bit generation and detection
  - Programmable stop bit, 1, 1.5, or 2 stop bit generation
- Supports IrDA SIR Function mode
  - Supports 3-/16-bit duration for normal mode
- Supports LIN function mode
  - Supports LIN master/Slave mode
  - Supports programmable break generation function for transmitter
  - Supports break detect function for receiver
- Supports RS-485 Function mode
  - Supports RS-485 9-bit mode
  - Supports hardware or software direct enable control provided by RTS pin

# nuvoTon

#### 5.12.3 Block Diagram

The UART clock control and block diagram are shown in Figure 5-67 and Figure 5-68.

Figure 5-69 UART Clock Control Diagram

Figure 5-70 UART Block Diagram

#### TX_FIFO

The transmitter is buffered with a 64/16 byte FIFO to reduce the number of interrupts presented to the CPU.

#### **RX_FIFO**

The receiver is buffered with a 64/16 byte FIFO (plus three error bits per byte) to reduce the number of interrupts presented to the CPU.

#### **TX shift Register**

This block is the shifting the transmitting data out serially control block.

#### **RX shift Register**

This block is the shifting the receiving data in serially control block.

#### **Modem Control Register**

This register controls the interface to the MODEM or data set (or a peripheral device emulating a MODEM).

#### Baud Rate Generator

Divide the external clock by the divisor to get the desired baud rate clock. Refer to baud rate equation.

#### IrDA Encode

This block is IrDA encode control block.

#### IrDA Decode

This block is IrDA decode control block.

#### **Control and Status Register**

This field is register set that including the FIFO control registers (UA_FCR), FIFO status registers (UA_FSR), and line control register (UA_LCR) for transmitter and receiver. The time out control register (UA_TOR) identifies the condition of time out interrupt. This register set also includes the interrupt enable register (UA_IER) and interrupt status register (UA_ISR) to enable or disable the responding interrupt and to identify the occurrence of the responding interrupt. There are seven types of interrupts, transmitter FIFO empty interrupt(INT_THRE), receiver threshold level reaching interrupt (INT_RDA), line status interrupt (parity error or framing error or break interrupt) (INT_RLS), time out interrupt (INT_TOUT), MODEM/Wake-up status interrupt (INT_MODEM), Buffer error interrupt (INT_BUF_ERR) and LIN receiver break field detected interrupt (INT_LIN_RX_BREAK).

## nuvoTon

The following diagram demonstrates the auto-flow control block diagram.

Figure 5-71 Auto Flow Control Block Diagram

#### 5.12.4 IrDA Mode

The UART supports IrDA SIR (Serial Infrared) Transmit Encoder and Receive Decoder, and IrDA mode is selected by setting the IrDA_EN bit in UA_FUN_SEL register.

In IrDA mode, the UA_BAUD [DIV_X_EN] register must be disabled.

Baud Rate = Clock / (16 * BRD), where BRD is Baud Rate Divider in UA_BAUD register.

The following diagram demonstrates the IrDA control block diagram.

Figure 5-72 IrDA Block Diagram

#### 5.12.4.1 IrDA SIR Transmit Encoder

The IrDA SIR Transmit Encoder modulates Non-Return-to Zero (NRZ) transmit bit stream output from UART. The IrDA SIR physical layer specifies use of Return-to-Zero, Inverted (RZI) modulation scheme which represent logic 0 as an infra light pulse. The modulated output pulse stream is transmitted to an external output driver and infrared Light Emitting Diode.

In normal mode, the transmitted pulse width is specified as 3/16 period of baud rate.

#### 5.12.4.2 IrDA SIR Receive Decoder

The IrDA SIR Receive Decoder demodulates the return-to-zero bit stream from the input detector and outputs the NRZ serial bits stream to the UART received data input. The decoder input is normally high in the idle state. (Because of this, IRCR bit 6 should be set as 1 by default)

A start bit is detected when the decoder input is LOW

#### 5.12.4.3 IrDA SIR Operation

The IrDA SIR Encoder/decoder provides functionality that converts between UART data stream and half duplex serial SIR interface. The following diagram is the IrDA encoder/decoder waveform:

## nuvoTon

No.

#### 5.12.5 LIN (Local Interconnection Network) Mode

The UART supports LIN function, and LIN mode is selected by setting the UA_FUN_SEL[1:0] to '01'. In LIN mode, each byte field is initialed by a start bit with value zero (dominant), followed by 8 data bits (LSB is first) and ended by 1 stop bit with value one (recessive) in accordance with the LIN standard. The following diagram is the structure of LIN function mode:

Figure 5-74 Structure of LIN Frame

The program flow of LIN Bus Transmit transfer (TX) is shown as follows:

- 1. Setting the UA_FUN_SEL[1:0] to '01' to enable LIN Bus mode.
- 2. Fill UA_LIN_BKFL in UA_LIN_BCNT to choose break field length. (The break field length is UA_LIN_BKFL + 2).
- 3. Setting the LIN_TX_EN bit in UA_LIN_BCNT register to start transmission (When break filed operation is finished, LIN_TX_EN will be cleared automatically).
- 4. Fill 0x55 to UA_THR to request synch field transmission.
- 5. Request Identifier Field transmission by writing the protected identifier value in the UA_THR
- 6. When the STOP bit of the last byte THR has been sent to bus, hardware will set flag TE_FLAG in UA_FSR to 1.
- 7. Fill N bytes data and Checksum to UA_THR then repeat step 5 and 6 to transmit the data.

The program flow of LIN Bus Receiver transfer (RX) is shown as follows:

- 1. Setting the UA_FUN_SEL[1:0] to '01' to enable LIN Bus mode.
- 2. Setting the LIN_RX_EN bit in UA_LIN_BCNT register to enable LIN RX mode.
- 3. Waiting for the flag LIN_RX_BREAK_IF in UA_ISR to check RX received Break field or not.
- 4. Waiting for the flag RDA_IF in UA_ISR and read back the UR_RBR register.

## nuvoton

#### 5.12.6 RS-485 Function Mode

The UART supports the RS-485 9-bit mode function. The RS-485 mode is selected by setting the UA FUN SEL register to select RS-485 function. The RS-485 driver control is implemented using the RTS control signal from an asynchronous serial port to enable the RS-485 driver. In RS-485 mode, many characteristics of the RX and TX are same as UART.

In RS-485 mode, the controller can configuration of it as an RS-485 addressable slave and the RS-485 master transmitter will identify an address character by setting the parity (9th bit) to 1. For data characters, the parity is set to 0. Software can use UA LCR register to control the 9-th bit (When the PBE, EPE and SPE are set, the 9-th bit is transmitted 0 and when PBE and SPE are set and EPE is cleared, the 9-th bit is transmitted 1). The Controller support three operation modes including RS-485 Normal Multidrop Operation Mode (NMM), RS-485 Auto Address Detection Operation Mode (AAD) and RS-485 Auto Direction Control Operation Mode (AUD). Software can choose any of the operation modes by programming UA_RS-485_CSR register, and software can drive the transfer delay time between the last stop bit leaving the TX-FIFO and the de-assertion of by setting UA_TOR [DLY] register.

#### RS-485 Normal Multidrop Operation Mode (NMM)

In RS-485 Normal Multidrop Operation mode, first, software must decide if the data before the address byte detected will be stored in RX-FIFO or not. If software want to ignore any data before address byte detected, the flow is set UART_FCR[RS485_RX_DIS] then enable UA_RS-485[RS485 NMM] and the receiver will ignore any data until an address byte is detected (bit9 =1) and the address byte data will be stored in the RX-FIFO. If software wants to receive any data before address byte detected, the flow is disable UART FCR [RS485 RX DIS] then enable UA RS-485[RS485 NMM] and the receiver will received any data. If an address byte is detected (bit9 =1), it will generator an interrupt to CPU and software can decide whether enable or disable receiver to accept the following data byte by setting UA RS-485 CSR [RX DIS]. If the receiver is be enabled, all received byte data will be accepted and stored in the RX-FIFO, and if the receiver is disabled, all received byte data will be ignore until the next address byte be detected. If software disable receiver by setting UA_RS-485_CSR [RX_DIS] register, when a next address byte be detected, the controller will clear the UA RS-485 CSR [RX DIS] bit and the address byte data will be stored in the RX-FIFO.

#### RS-485 Auto Address Detection Operation Mode (AAD)

In RS-485 Auto Address Detection Operation mode, the receiver will ignore any data until an address byte is detected (bit9 =1) and the address byte data matches the UA_RS-485[ADDR MATCH] value. The address byte data will be stored in the RX-FIFO. The all received byte data will be accepted and stored in the RX-FIFO until and address byte data not match the UA RS-485[ADDR MATCH] value.

#### RS-485 Auto Direction Mode (AUD)

Another option function of RS-485 controllers is RS-485 auto direction control function. The RS-485 driver control is implemented using the RTS control signal from an asynchronous serial port to enable the RS-485 driver. The RTS line is connected to the RS-485 driver enable such that setting the RTS line to high (logic 1) enables the RS-485 driver. Setting the RTS line to low (logic 0) puts the driver into the tri-state condition. User can setting LEV_RTS in UA_MCR register to change the RTS driving level. NOTOS.

Aug 04, 2013

Program Sequence example:

- 1. Program FUN_SEL in UA_FUN_SEL to select RS-485 function.
- 2. Program the RX_DIS bit in UA_FCR register to determine enable or disable RS-485 receiver
- 3. Program the RS-485_NMM or RS-485_AAD mode.
- 4. If the RS-485_AAD mode is selected, the ADDR_MATCH is programmed for auto address match value.
- 5. Determine auto direction control by programming RS-485_AUD.

	20 00	Transmitter FIFO Empty (Read Only)
10.01	NALL	This bit indicates TX FIFO empty or not.
[22]	TX_EMPTY	When the last byte of TX FIFO has been transferred to Transmitter Shift Register, hardware sets this bit high. It will be cleared when writing data into THR (TX FIFO not empty).
[21:16]	TX_POINTER	TX FIFO Pointer (Read Only)
ľ, í		This field indicates the TX FIFO Buffer Pointer. When CPU writes one byte into

		UA_THR, TX_POINTER increases one. When one byte of TX FIFO is transferred to Transmitter Shift Register, TX_POINTER decreases one.
		The Maximum value shows in TX_POINTER is 63/15/15 (UART0/UART1/UART2). When the using level of TX FIFO Buffer equal to 64/16/16, the TX_FULL bit is set to 1 and TX_POINTER will show 0. As one byte of TX FIFO is transferred to Transmitter Shift Register, the TX_FULL bit is clear to 0 and TX_POINTER will show 63/15/15 (UART0/UART1/UART2).
		Receiver FIFO Full (Read Only)
[15]	RX_FULL	This bit initiates RX FIFO full or not.
[]		This bit is set when the number of usage in RX FIFO Buffer is equal to 64/16/16(UART0/UART1/UART2); otherwise, it is cleared by hardware.
 		Receiver FIFO Empty (Read Only)
 [14]	RX_EMPTY	This bit initiate RX FIFO empty or not.
		When the last byte of RX FIFO has been read by CPU, hardware sets this bit high. It will be cleared when UART receives any new data.
		RX FIFO Pointer (Read Only)
		This field indicates the RX FIFO Buffer Pointer. When UART receives one byte from external device, RX_POINTER increases one. When one byte of RX FIFO is read by CPU, RX_POINTER decreases one.
[13:8]	RX_POINTER	The Maximum value shows in RX_POINTER is 63/15/15 (UART0/UART1/UART2). When the using level of RX FIFO Buffer equal to 64/16/16, the RX_FULL bit is set to 1 and RX_POINTER will show 0. As one byte of RX FIFO is read by CPU, the RX_FULL bit is clear to 0 and RX_POINTER will show 63/15/15 (UART0/UART1/UART2).
 [7]	Reserved	Reserved
[6]	BIF	Break Interrupt Flag (Read Only) This bit is set to a logic 1 whenever the received data input(RX) is held in the "spacing state" (logic 0) for longer than a full word transmission time (that is, the total time of "start bit" + data bits + parity + stop bits) and is reset whenever the CPU writes 1 to this bit.
		Note: This bit is read only, but can be cleared by writing '1' to it.
		Framing Error Flag (Read Only)
[5]	FEF	This bit is set to logic 1 whenever the received character does not have a valid "stop bit" (that is, the stop bit following the last data bit or parity bit is detected as a logic 0), and is reset whenever the CPU writes 1 to this bit.
S.		Note: This bit is read only, but can be cleared by writing '1' to it.
A.		Parity Error Flag (Read Only)
[4]	PEF	This bit is set to logic 1 whenever the received character does not have a valid "parity bit", and is reset whenever the CPU writes 1 to this bit.
Val.	12	Note: This bit is read only, but can be cleared by writing '1' to it.
m.		RS-485 Address Byte Detection Flag (Read Only)
[3]	RS485_ADD_DETF	This bit is set to logic 1 and set UA_ALT_CSR [RS-485_ADD_EN] whenever in RS- 485 mode the receiver detect any address byte received address byte character (bit9 = '1') bit", and it is reset whenever the CPU writes 1 to this bit.
	20 0	Note: This field is used for RS-485 function mode.
	To	Note: This bit is read only, but can be cleared by writing '1' to it.
[2:1]	Reserved	Reserved
[0]	()) () () () () () () () () (

This bit is set when RX FIFO overflow.
If the number of bytes of received data is greater than RX_FIFO (UA_RBR) size, 64/16 bytes of UART0/UART1, this bit will be set.
Note: This bit is read only, but can be cleared by writing '1' to it.

	-		
			In DMA Mode, Buffer Error Interrupt Flag (Read Only)
	[21]	hw_buf_err_ If	This bit is set when the TX or RX FIFO overflows (TX_OVER_IF or RX_OVER_IF is set). When BUF_ERR_IF is set, the transfer maybe is not correct. If UA_IER [BUF_ERR_IEN] is enabled, the buffer error interrupt will be generated.
			Note: This bit is cleared when both TX_OVER_IF and RX_OVER_IF are cleared.
			In DMA Mode, Time Out Interrupt Flag (Read Only)
	[20]	HW_TOUT_IF	This bit is set when the RX FIFO is not empty and no activities occurred in the RX FIFO and the time out counter equal to TOIC. If UA_IER [TOUT_IEN] is enabled, the Tout interrupt will be generated.
			Note: This bit is read only and user can read UA_RBR (RX is in active) to clear it.
			In DMA Mode, MODEM Interrupt Flag (Read Only) (Not Available in UART2 Channel)
	[19]	HW_MODEM_IF	This bit is set when the CTS pin has state change (DCTSF=1). If UA_IER [MODEM_IEN] is enabled, the Modem interrupt will be generated.
			Note: This bit is read only and reset to 0 when bit DCTSF is cleared by a write 1 on DCTSF.
			In DMA Mode, Receive Line Status Flag (Read Only)
	[18]	HW_RLS_IF	This bit is set when the RX receive data have parity error, framing error or break error (at least one of 3 bits, BIF, FEF and PEF, is set). If UA_IER [RLS_IEN] is enabled, the RLS interrupt will be generated.
			Note: In RS-485 Function mode, this field includes "receiver detect any address byte received address byte character (bit9 = '1') bit".
			Note: This bit is read only and reset to 0 when all bits of BIF, FEF and PEF are cleared.
	[17:16]	Reserved	Reserved
			LIN Bus RX Break Field Detected Interrupt Indicator (Read Only)
	[15]	LIN_RX_BREAK	This bit is set if LIN_RX_BRK_IEN and LIN_RX_BREAK_IF are both set to 1.
	[15]	_INT	1 = LIN RX Break interrupt is generated
			0 = No LIN RX Break interrupt is generated
	[14]	Reserved	Reserved
			Buffer Error Interrupt Indicator (Read Only)
	[13]		This bit is set if BUF_ERR_IEN and BUF_ERR_IF are both set to 1.
	[13]	BUF_ERR_INT	1 = The buffer error interrupt is generated
	300		0 = No buffer error interrupt is generated
			Time Out Interrupt Indicator (Read Only)
	[12]	TOUT_INT	This bit is set if TOUT_IEN and TOUT_IF are both set to 1.
			1 = Tout interrupt is generated
	Un	0	0 = No Tout interrupt is generated
	Sec.	a Ca	MODEM Status Interrupt Indicator (Read Only) (Not Available in UART2 Channel)
	[11]	MODEM INT	This bit is set if MODEM_IEN and MODEM_IF are both set to 1.
	[11]		1 = Modem interrupt is generated
		22	0 = No Modem interrupt is generated
		90	Receive Line Status Interrupt Indicator (Read Only).
	[10]	RLS_INT	This bit is set if RLS_IEN and RLS_IF are both set to 1.
		1	

			1 = RLS interrupt is generated
			0 = No RLS interrupt is generated
			Transmit Holding Register Empty Interrupt Indicator (Read Only).
	[0]		This bit is set if THRE_IEN and THRE_IF are both set to 1.
	[9]	THRE_INT	1 = THRE interrupt is generated
			0 = No THRE interrupt is generated
			Receive Data Available Interrupt Indicator (Read Only).
	[0]	RDA_INT	This bit is set if RDA_IEN and RDA_IF are both set to 1.
	[8]		1 = RDA interrupt is generated
			0 = No RDA interrupt is generated
			LIN Bus RX Break Field Detected Flag (Read Only)
	[7]	LIN_RX_BREAK _IF	This bit is set when RX received LIN Break Field. If UA_IER [LIN_RX_BRK_IEN] is enabled the LIN RX Break interrupt will be generated.
			Note: This bit is read only, but can be cleared by writing '1' to it.
	[6]	Reserved	Reserved
			Buffer Error Interrupt Flag (Read Only)
	[5] BUF_ERR_II	BUF_ERR_IF	This bit is set when the TX or RX FIFO overflows or Break Interrupt Flag or Parity Erro Flag or Frame Error Flag (TX_OVER_IF or RX_OVER_IF or BIF or PEF or FEF) is set When BUF_ERR_IF is set, the transfer is not correct. If UA_IER [BUF_ERR_IEN] is enabled, the buffer error interrupt will be generated.
			Time Out Interrupt Flag (Read Only)
	[4]	TOUT_IF	This bit is set when the RX FIFO is not empty and no activities occurred in the RX FIFO and the time out counter equal to TOIC. If UA_IER [TOUT_IEN] is enabled, the Tout interrupt will be generated.
			Note: This bit is read only and user can read UA_RBR (RX is in active) to clear it.
			MODEM Interrupt Flag (Read Only) (Not Available in UART2 Channel)
	[3] MOD	MODEM_IF	This bit is set when the CTS pin has state change (DCTSF=1). If UA_IER [MODEM_IEN] is enabled, the Modem interrupt will be generated.
			Note: This bit is read only and reset to 0 when bit DCTSF is cleared by a write 1 on DCTSF.
			Receive Line Interrupt Flag (Read Only).
	[2]	RLS_IF	This bit is set when the RX receive data have parity error, framing error or break error (at least one of 3 bits, BIF, FEF and PEF, is set). If UA_IER [RLS_IEN] is enabled, the RLS interrupt will be generated.
	N. N	S.	Note: In RS-485 Function mode, this field include "receiver detect any address byte received address byte character (bit9 = '1') bit".
	S		Note: This bit is read only and reset to 0 when all bits of BIF, FEF and PEF are cleare
	0	200	Transmit Holding Register Empty Interrupt Flag (Read Only).
	[1]	THRE_IF	This bit is set when the last data of TX FIFO is transferred to Transmitter Shift Registe If UA_IER [THRE_IEN] is enabled, the THRE interrupt will be generated.
	6	200	Note: This bit is read only and it will be cleared when writing data into THR (TX FIFO not empty).
		0	Receive Data Available Interrupt Flag (Read Only).
	[0] RDA_IF	RDA_IF	When the number of bytes in the RX FIFO equals the RFITL then the RDA_IF will be set. If UA_IER [RDA_IEN] is enabled, the RDA interrupt will be generated.

5.13 Controller Area Network (CAN)

5.13.1 Overview

The C_CAN consists of the CAN Core, Message RAM, Message Handler, Control Registers and Module Interface (Refer Figure 5-76). The CAN Core performs communication according to the CAN protocol version 2.0 part A and B. The bit rate can be programmed to values up to 1MBit/s. For the connection to the physical layer, additional transceiver hardware is required.

For communication on a CAN network, individual Message Objects are configured. The Message Objects and Identifier Masks for acceptance filtering of received messages are stored in the Message RAM. All functions concerning the handling of messages are implemented in the Message Handler. These functions include acceptance filtering, the transfer of messages between the CAN Core and the Message RAM, and the handling of transmission requests as well as the generation of the module interrupt.

The register set of the C_CAN can be accessed directly by the software through the module interface. These registers are used to control/configure the CAN Core and the Message Handler and to access the Message RAM.

5.13.2 Features

- Supports CAN protocol version 2.0 part A and B
- Bit rates up to 1 MBit/s
- 32 Message Objects
- Each Message Object has its own identifier mask
- Programmable FIFO mode (concatenation of Message Objects)
- Maskable interrupt
- Disabled Automatic Re-transmission mode for Time Triggered CAN applications
- Programmable loop-back mode for self-test operation
- 16-bit module interfaces to the AMBA APB bus
- Supports wake-up function

5.13.3 Block Diagram

The C_CAN interfaces with the AMBA APB bus. Figure 5-76 shows the block diagram of the C_CAN.

CAN Core

CAN Protocol Controller and Rx/Tx Shift Register for serial/parallel conversion of messages.

Message RAM

Stores Message Objects and Identifier Masks

Registers

All registers used to control and to configure the C_CAN.

• Message Handler

State Machine that controls the data transfer between the Rx/Tx Shift Register of the CAN Core and the Message RAM as well as the generation of interrupts as programmed in the Control and Configuration Registers.

• Module Interface

C_CAN interfaces to the AMBA APB 16-bit bus from ARM.

Figure 5-76 CAN Peripheral Block Diagram

5.13.4 Functional Description

5.13.4.1 Software Initialization

The software initialization is started by setting the **Init** bit in the CAN Control Register, either by a software or a hardware reset, or by going to *Bus_Off* state.

While the **Init** bit is set, all messages transfer to and from the CAN bus are stopped and the status of the **CAN_TX** output pin is recessive (HIGH). The Error Management Logic (EML) counters are unchanged. Setting the **Init** bit does not change any configuration register.

To initialize the CAN Controller, software has to set up the Bit Timing Register and each Message Object. If a Message Object is not required, the corresponding **MsgVal** bit should be cleared. Otherwise, the entire Message Object has to be initialized.

Access to the Bit Timing Register and to the Baud Rate Prescaler Extension Register for configuring bit timing is enabled when both the **Init** and **CCE** bits in the CAN Control Register are set.

Resetting the Init bit (by software only) finishes the software initialization. Later, the Bit Stream Processor (BSP) (see Section 5.13.6.10: Configuring the Bit Timing) synchronizes itself to the data transfer on the CAN bus by waiting for the occurrence of a sequence of 11 consecutive recessive bits (\equiv Bus Idle) before it can take part in bus activities and start the message transfer.

The initialization of the Message Objects is independent of Init and can be done on the fly, but the Message Objects should all be configured to particular identifiers or set to not valid before the BSP starts the message transfer.

To change the configuration of a Message Object during normal operation, the software has to start by resetting the corresponding **MsgVal** bit. When the configuration is completed, **MsgVal** is set again.

5.13.4.2 CAN Message Transfer

Once the C_CAN is initialized and Init bit is reset to 0, the C_CAN Core synchronizes itself to the CAN bus and starts the message transfer.

Received messages are stored in their appropriate Message Objects if they pass the Message Handler's acceptance filtering. The whole message including all arbitration bits, DLC and eight data bytes are stored in the Message Object. If the Identifier Mask is used, the arbitration bits which are masked to "don't care" may be overwritten in the Message Object.

Software can read or write each message any time through the Interface Registers and the Message Handler guarantees data consistency in case of concurrent accesses.

Messages to be transmitted are updated by the application software. If a permanent Message Object (arbitration and control bits are set during configuration) exists for the message, only the data bytes are updated and the **TxRqst** bit with **NewDat** bit are set to start the transmission. If several transmit messages are assigned to the same Message Object (when the number of Message Objects is not sufficient), the whole Message Object has to be configured before the transmission of this message is requested.

The transmission of any number of Message Objects may be requested at the same time. Message objects are transmitted subsequently according to their internal priority. Messages may be updated or set to not valid any time, even when their requested transmission is still pending. The old data will be discarded when a message is updated before its pending transmission has started.

Depending on the configuration of the Message Object, the transmission of a message may be requested autonomously by the reception of a remote frame with a matching identifier.

ηυνοτοη

5.13.4.3 Disabled Automatic Retransmission

In accordance with the CAN Specification (see ISO11898, 6.3.3 Recovery Management), the C_CAN provides means for automatic retransmission of frames that have lost arbitration or have been disturbed by errors during transmission. The frame transmission service will not be confirmed to the user before the transmission is successfully completed. This means that, by default, automatic retransmission is enabled. It can be disabled to enable the C_CAN to work within a Time Triggered CAN (TTCAN, see ISO11898-1) environment.

The Disabled Automatic Retransmission mode is enabled by setting the Disable Automatic Retransmission (**DAR**) bit in the CAN Control Register to one. In this operation mode, the programmer has to consider the different behavior of bits TxRqst and NewDat in the Control Registers of the Message Buffers:

• When a transmission starts, bit TxRqst of the respective Message Buffer is cleared, while bit NewDat remains set.

- When the transmission completed successfully, bit NewDat is cleared.
- · When a transmission fails (lost arbitration or error), bit NewDat remains set.
- To restart the transmission, the software should set the bit TxRqst again.

5.13.5 Test Mode

Test Mode is entered by setting the **Test** bit in the CAN Control Register. In Test Mode, bits **Tx1**, **Tx0**, **LBack**, **Silent** and **Basic** in the Test Register are writeable. Bit **Rx** monitors the state of the **CAN_RX** pin and therefore is only readable. All Test Register functions are disabled when the Test bit is cleared.

5.13.5.1 Silent Mode

The CAN Core can be set in Silent Mode by programming the **Silent** bit in the Test Register to one. In Silent Mode, the C_CAN is able to receive valid data frames and valid remote frames, but it sends only recessive bits on the CAN bus and it cannot start a transmission. If the CAN Core is required to send a dominant bit (ACK bit, Error Frames), the bit is rerouted internally so that the CAN Core monitors this dominant bit, although the CAN bus may remain in recessive state. The Silent Mode can be used to analysis the traffic on a CAN bus without affecting it by the transmission of *dominant* bits. Figure 5-77 shows the connection of signals **CAN_TX** and **CAN_RX** to the CAN Core in Silent Mode.

5.13.5.2 Loop Back Mode

The CAN Core can be set in Loop Back Mode by programming the Test Register bit **LBack** to one. In Loop Back Mode, the CAN Core treats its own transmitted messages as received messages and stores them into a Receive Buffer (if they pass acceptance filtering).Figure 5-78 shows the connection of signals, **CAN_TX** and **CAN_RX**, to the CAN Core in Loop Back Mode.

Figure 5-78 CAN Core in Loop Back Mode

This mode is provided for self-test functions. To be independent from external stimulation, the CAN Core ignores acknowledge errors (recessive bit sampled in the acknowledge slot of a data/ remote frame) in Loop Back Mode. In this mode, the CAN Core performs an internal feedback from its Tx output to its Rx input. The actual value of the **CAN_RX** input pin is disregarded by the CAN Core. The transmitted messages can be monitored on the **CAN_TX** pin.

5.13.5.3 Loop Back Combined with Silent Mode

It is also possible to combine Loop Back Mode and Silent Mode by programming bits LBack and Silent to one at the same time. This mode can be used for a "Hot Selftest", which means that C_CAN can be tested without affecting a running CAN system connected to the CAN_TX and CAN_RX pins. In this mode, the CAN_RX pin is disconnected from the CAN Core and the CAN_TX pin is held recessive. Figure 5-79 shows the connection of signals CAN_TX and CAN_RX to the CAN Core in case of the combination of Loop Back Mode with Silent Mode.

Figure 5-79 CAN Core in Loop Back Mode Combined with Silent Mode

5.13.5.4 Basic Mode

The CAN Core can be set in Basic Mode by programming the Test Register bit **Basic** to one. In this mode, the C_CAN runs without the Message RAM.

The IF1 Registers are used as Transmit Buffer. The transmission of the contents of the IF1 Registers are requested by writing the Busy bit of the IF1 Command Request Register to one. The IF1 Registers are locked while the **Busy** bit is set. The Busy bit indicates that the transmission is pending.

As soon the CAN bus is idle, the IF1 Registers are loaded into the shift register of the CAN Core and the transmission is started. When the transmission has been completed, the **Busy** bit is reset and the locked IF1 Registers are released.

A pending transmission can be aborted at any time by resetting the **Busy** bit in the IF1 Command Request Register while the IF1 Registers are locked. If the software has reset the Busy bit, a possible retransmission in case of lost arbitration or in case of an error is disabled.

The IF2 Registers are used as a Receive Buffer. After the reception of a message the contents of the shift register is stored into the IF2 Registers, without any acceptance filtering.

Additionally, the actual contents of the shift register can be monitored during the message transfer. Each time a read Message Object is initiated by writing the **Busy** bit of the IF2 Command Request Register to one, the contents of the shift register are stored into the IF2 Registers.

In Basic Mode, the evaluation of all Message Object related control and status bits and the control bits of the IFn Command Mask Registers are turned off. The message number of the Command request registers is not evaluated. The **NewDat** and **MsgLst** bits in the IF2 Message Control Register retain their function, **DLC3-0** indicates the received DLC, and the other control bits are read as '0'.

5.13.5.5 Software Control of CAN_TX Pin

Four output functions are available for the CAN transmit pin, **CAN_TX**. In addition to its default function (serial data output), the CAN transmit pin can drive the CAN Sample Point signal to monitor CAN_Core's bit timing and it can drive constant dominant or recessive values. The latter two functions, combined with the readable CAN receive pin **CAN_RX**, can be used to check the physical layer of the CAN bus.

The output mode for the **CAN_TX** pin is selected by programming the **Tx1** and **Tx0** bits of the CAN Test Register.

The three test functions of the **CAN_TX** pin interfere with all CAN protocol functions. **CAN_TX** must be left in its default function when CAN message transfer or any of the test modes (Loop Back Mode, Silent Mode, or Basic Mode) are selected.

5.13.6 CAN Communications

5.13.6.1 Managing Message Objects

The configuration of the Message Objects in the Message RAM (with the exception of the bits he CAN Control Regist **MsgVal**, **NewDat**, **IntPnd**, and **TxRqst**) will not be affected by resetting the chip. All the Message Objects must be initialized by the application software or they must be "not valid" (**MsgVal** = '0') and the bit timing must be configured before the application software clears the Init bit in ter.

The configuration of a Message Object is done by programming Mask, Arbitration, Control and Data fields of one of the two interface registers to the desired values. By writing to the corresponding IFn Command Request Register, the IFn Message Buffer Registers are loaded

into the addressed Message Object in the Message RAM.

When the Init bit in the CAN Control Register is cleared, the CAN Protocol Controller state machine of the CAN_Core and the state machine of the Message Handler control the internal data flow of the C_CAN. Received messages that pass the acceptance filtering are stored into the Message RAM, messages with pending transmission request are loaded into the CAN_Core's Shift Register and are transmitted through the CAN bus.

The application software reads received messages and updates messages to be transmitted through the IFn Interface Registers. Depending on the configuration, the application software is interrupted on certain CAN message and CAN error events.

5.13.6.2 Message Handler State Machine

The Message Handler controls the data transfer between the Rx/Tx Shift Register of the CAN Core, the Message RAM and the IFn Registers.

The Message Handler FSM controls the following functions:

- Data Transfer from IFn Registers to the Message RAM
- Data Transfer from Message RAM to the IFn Registers
- Data Transfer from Shift Register to the Message RAM
- Data Transfer from Message RAM to Shift Register
- Data Transfer from Shift Register to the Acceptance Filtering unit
- Scanning of Message RAM for a matching Message Object
- Handling of TxRqst flags
- Handling of interrupts.

5.13.6.2.1 Data Transfer from/to Message RAM

When the application software initiates a data transfer between the IFn Registers and Message RAM, the Message Handler sets the Busy bit in the respective Command Request Register (CAN_IFn_CRR) to '1'. After the transfer has completed, the Busy bit is again cleared (see Figure 5-80).

The respective Command Mask Register specifies whether a complete Message Object or only parts of it will be transferred. Due to the structure of the Message RAM, it is not possible to write single bits/bytes of one Message Object. It is always necessary to write a complete Message Object into the Message RAM. Therefore, the data transfer from the IFn Registers to the Message RAM requires a read-modify-write cycle. First, those parts of the Message Object that are not to be changed are read from the Message RAM and then the complete contents of the Message Buffer Registers are written into the Message Object.

nuvoTon

Figure 5-80 Data Transfer between IFn Registers and Message

After a partial write of a Message Object, the Message Buffer Registers that are not selected in the Command Mask Register will set the actual contents of the selected Message Object.

After a partial read of a Message Object, the Message Buffer Registers that are not selected in the Command Mask Register will be left unchanged.

5.13.6.2.2 Message Transmission

If the shift register of the CAN Core cell is ready for loading and if there is no data transfer between the IFn Registers and Message RAM, the **MsgVal** bits in the Message Valid Register and **TxRqst** bits in the Transmission Request Register are evaluated. The valid Message Object with the highest priority pending transmission request is loaded into the shift register by the Message Handler and the transmission is started. The **NewDat** bit of the Message Object is reset.

After a successful transmission and also if no new data was written to the Message Object (**NewDat** = '0') since the start of the transmission, the **TxRqst** bit of the Message Control register (CAN_IFn_MCR) will be reset. If TxIE bit of the Message Control register (CAN_IFn_MCR) is set, **IntPnd** bit of the Interrupt Identifier register will be set after a successful transmission. If the C_CAN has lost the arbitration or if an error occurred during the transmission, the message will be retransmitted as soon as the CAN bus is free again. Meanwhile, if the transmission of a message with higher priority has been requested, the messages will be transmitted in the order of their priority.

5.13.6.2.3 Acceptance Filtering of Received Messages

When the arbitration and control field (Identifier + IDE + RTR + DLC) of an incoming message is completely shifted into the Rx/Tx Shift Register of the CAN Core, the Message Handler FSM starts the scanning of the Message RAM for a matching valid Message Object.

To scan the Message RAM for a matching Message Object, the Acceptance Filtering unit is loaded with the arbitration bits from the CAN Core shift register. The arbitration and mask fields (including **MsgVal**, **UMask**, **NewDat**, and **EoB**) of Message Object 1 are then loaded into the Acceptance Filtering unit and compared with the arbitration field from the shift register. This is repeated with each following Message Object until a matching Message Object is found or until the end of the Message RAM is reached.

If a match occurs, the scan is stopped and the Message Handler FSM proceeds depending on the type of frame (Data Frame or Remote Frame) received.

Reception of Data Frame

The Message Handler FSM stores the message from the CAN Core shift register into the respective Message Object in the Message RAM. Not only the data bytes, but all arbitration bits and the Data Length Code are stored into the corresponding Message Object. This is done to keep the data bytes connected with the identifier even if arbitration mask registers are used.

The **NewDat** bit is set to indicate that new data (not yet seen by the software) has been received. The application software should reset **NewDat** bit when the Message Object has been read. If at the time of reception, the **NewDat** bit was already set, **MsgLst** is set to indicate that the previous data (supposedly not seen by the software) is lost. If the **RxIE** bit is set, the **IntPnd** bit is set, causing the Interrupt Register to point to this Message Object.

The **TxRqst** bit of this Message Object is reset to prevent the transmission of a Remote Frame, while the requested Data Frame has just been received.

Reception of Remote Frame

When a Remote Frame is received, three different configurations of the matching Message Object have to be considered:

1) Dir = '1' (direction = transmit), RmtEn = '1', UMask = '1' or'0'

At the reception of a matching Remote Frame, the TxRqst bit of this Message Object is set. The rest of the Message Object remains unchanged.

2) Dir = '1' (direction = transmit), RmtEn = '0', UMask ='0'

At the reception of a matching Remote Frame, the TxRqst bit of this Message Object remains unchanged; the Remote Frame is ignored.

3) Dir = '1' (direction = transmit), RmtEn = '0', UMask ='1'

At the reception of a matching Remote Frame, the **TxRqst** bit of this Message Object is reset. The arbitration and control field (Identifier + IDE + RTR + DLC) from the shift register is stored in the Message Object of the Message RAM and the **NewDat** bit of this Message Object is set. The data field of the Message Object remains unchanged; the Remote Frame is treated similar to a received Data Frame.

5.13.6.2.4 Receive/Transmit Priority

The receive/transmit priority for the Message Objects is attached to the message number. Message Object 1 has the highest priority, while Message Object 32 has the lowest priority. If more than one transmission request is pending, they are serviced due to the priority of the corresponding Message Object

5.13.6.3 Configuring a Transmit Object

Table 5-14 shows how a Transmit Object should be initialized.

Ms	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	1	0	0	0	appl.	0	appl.	0

Table 5-14 Initialization of a Transmit Object

Note: appl. = application software.

The Arbitration Register values (**ID28-0** and **Xtd** bit) are provided by the application. They define the identifier and type of the outgoing message. If an 11-bit Identifier ("Standard Frame") is used, it is programmed to ID28 - ID18. The ID17 - ID0 can then be disregarded.

If the **TxIE** bit is set, the **IntPnd** bit will be set after a successful transmission of the Message Object.

If the **RmtEn** bit is set, a matching received Remote Frame will cause the **TxRqst** bit to be set; the Remote Frame will autonomously be answered by a Data Frame.

The Data Register values (**DLC3-0**, **Data0-7**) are provided by the application, **TxRqst** and **RmtEn** may not be set before the data is valid.

The Mask Registers (**Msk28-0**, **UMask**, **MXtd**, and **MDir** bits) may be used (**UMask**='1') to allow groups of Remote Frames with similar identifiers to set the **TxRqst** bit. The Dir bit should not be masked.

5.13.6.4 Updating a Transmit Object

The software may update the data bytes of a Transmit Object any time through the IFn Interface registers, neither **MsgVal** nor **TxRqst** have to be reset before the update.

Even if only a part of the data bytes are to be updated, all four bytes of the corresponding IFn Data A Register or IFn Data B Register have to be valid before the contents of that register are transferred to the Message Object. Either the application software has to write all four bytes into the IFn Data Register or the Message Object is transferred to the IFn Data Register before the software writes the new data bytes.

nuvoton

When only the (eight) data bytes are updated, first 0x0087 is written to the Command Mask Register and then the number of the Message Object is written to the Command Request Register, concurrently updating the data bytes and setting **TxRqst**.

To prevent the reset of **TxRqst** at the end of a transmission that may already be in progress while the data is updated, **NewDat** has to be set together with **TxRqst**.

When **NewDat** is set together with **TxRqst**, **NewDat** will be reset as soon as the new transmission has started.

5.13.6.5 Configuring a Receive Object

Table 5-15 shows how a Receive Object should be initialized.

MsgVal	Arb	Data	Mask	EoB	Dir	NewDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
1	appl.	appl.	appl.	1	0	0	0	appl.	0	0	0	00

Table 5-15 Initialization of a Receive Object

The Arbitration Registers values **(ID28-0** and **Xtd** bit) are provided by the application. They define the identifier and type of accepted received messages. If an 11-bit Identifier ("Standard Frame") is used, it is programmed to ID28 - ID18. Then ID17 - ID0 can be disregarded. When a Data Frame with an 11-bit Identifier is received, ID17 - ID0 will be set to '0'.

If the **RxIE** bit is set, the **IntPnd** bit will be set when a received Data Frame is accepted and stored in the Message Object.

The Data Length Code (DLC3-0) is provided by the application. When the Message Handler stores a Data Frame in the Message Object, it will store the received Data Length Code and eight data bytes. If the Data Length Code is less than 8, the remaining bytes of the Message Object will be overwritten by unspecified values.

The Mask Registers (Msk28-0, **UMask**, **MXtd**, and **MDir** bits) may be used (**UMask**='1') to allow groups of Data Frames with similar identifiers to be accepted. The Dir bit should not be masked in typical applications.

5.13.6.6 Handling Received Messages

The application software may read a received message any time through the IFn Interface registers. The data consistency is guaranteed by the Message Handler state machine.

Typically, the software will write first 0x007F to the Command Mask Register and then the number of the Message Object to the Command Request Register. This combination will transfer the whole received message from the Message RAM into the Message Buffer Register. Additionally, the bits **NewDat** and **IntPnd** are cleared in the Message RAM (not in the Message Buffer).

If the Message Object uses masks for acceptance filtering, the arbitration bits shows which of the matching messages have been received.

The actual value of NewDat shows whether a new message has been received since the last

time this Message Object was read. The actual value of **MsgLst** shows whether more than one message has been received since the last time this Message Object was read. **MsgLst** will not be automatically reset.

By means of a Remote Frame, the software may request another CAN node to provide new data for a receive object. Setting the **TxRqst** bit of a receive object will cause the transmission of a Remote Frame with the receive object's identifier. This Remote Frame triggers the other CAN node to start the transmission of the matching Data Frame. If the matching Data Frame is received before the Remote Frame could be transmitted, the **TxRqst** bit is automatically reset.

5.13.6.7 Configuring a FIFO Buffer

With the exception of the EoB bit, the configuration of Receive Objects belonging to a FIFO Buffer is the same as the configuration of a (single) Receive Object, see Section 5.13.6.5: Configuring a Receive Object.

To concatenate two or more Message Objects into a FIFO Buffer, the identifiers and masks (if used) of these Message Objects have to be programmed to matching values. Due to the implicit priority of the Message Objects, the Message Object with the lowest number will be the first Message Object of the FIFO Buffer. The **EoB** bit of all Message Objects of a FIFO Buffer except the last have to be programmed to zero. The **EoB** bits of the last Message Object of a FIFO Buffer is set to one, configuring it as the End of the Block.

5.13.6.8 Receiving Messages with FIFO Buffers

Received messages with identifiers matching to a FIFO Buffer are stored into a Message Object of this FIFO Buffer starting with the Message Object with the lowest message number.

When a message is stored into a Message Object of a FIFO Buffer, the **NewDat** bit of this Message Object is set. By setting **NewDat** while **EoB** is zero, the Message Object is locked for further write access by the Message Handler until the application software has written the NewDat bit back to 0.

Messages are stored into a FIFO Buffer until the last Message Object of this FIFO Buffer is reached. If none of the preceding Message Objects is released by writing **NewDat** to 0, all further messages for this FIFO Buffer will be written into the last Message Object of the FIFO Buffer and therefore overwrite previous messages.

5.13.6.8.1 Reading from a FIFO Buffer

When the application software transfers the contents of a Message Object to the IFn Message Buffer register by writing its number to the IFn Command Request Register, the corresponding Command Mask Register should be programmed in such a way that bits **NewDat** and **IntPnd** are reset to 0 (**TxRqst/NewDat** = '1' and **CirintPnd** = '1'). The values of these bits in the Message Control Register always reflect the status before resetting the bits.

To assure the correct function of a FIFO Buffer, the application software should read the Message Objects starting at the FIFO Object with the lowest message number.

Figure 5-81 shows how a set of Message Objects which are concatenated to a FIFO Buffer can be handled by the application software.

NuMicro[™] NUC130/NUC140 Technical Reference Manual

nuvoTon

5.13.6.9 Handling Interrupts

If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the application software has cleared it.

The Status Interrupt has the highest priority. Among the message interrupts, interrupt priority of the Message Object decreases with increasing message number.

A message interrupt is cleared by clearing the **IntPnd** bit of the Message Object. The Status Interrupt is cleared by reading the Status Register.

The interrupt identifier, **Intld**, in the Interrupt Register, indicates the cause of the interrupt. When no interrupt is pending, the register will hold the value zero. If the value of the Interrupt Register is different from zero, then there is an interrupt pending and, if IE is set, the CAN_INT interrupt signal is active. The interrupt remains active until the Interrupt Register is back to value zero (the cause of the interrupt is reset) or until IE is reset.

The value 0x8000 indicates that an interrupt is pending because the CAN Core has updated (not necessarily changed) the Status Register (Error Interrupt or Status Interrupt). This interrupt has the highest priority. The application software can update (reset) the status bits **RxOk**, **TxOk** and LEC, but a write access of the software to the Status Register can never generate or reset an interrupt.

All other values indicate that the source of the interrupt is one of the Message Objects. **Intld** points to the pending message interrupt with the highest interrupt priority.

The application software controls whether a change of the Status Register may cause an interrupt (bits EIE and SIE in the CAN Control Register) and whether the interrupt line becomes active when the Interrupt Register is different from zero (bit IE in the CAN Control Register). The Interrupt Register will be updated even when IE is reset.

The application software has two possibilities to follow the source of a message interrupt. First, it can follow the **Intld** in the Interrupt Register and second it can poll the Interrupt Pending Register.

An interrupt service routine that is reading the message that is the source of the interrupt may read the message and reset the Message Object's **IntPnd** at the same time (bit **CIrIntPnd** in the Command Mask Register). When **IntPnd** is cleared, the Interrupt Register will point to the next Message Object with a pending interrupt.

5.13.6.10 Configuring the Bit Timing

Even if minor errors in the configuration of the CAN bit timing do not result in immediate failure, the performance of a CAN network can be reduced significantly.

In many cases, the CAN bit synchronization will amend a faulty configuration of the CAN bit timing to such a degree that only occasionally an error frame is generated. However, in the case of arbitration, when two or more CAN nodes simultaneously try to transmit a frame, a misplaced sample point may cause one of the transmitters to become error passive.

The analysis of such sporadic errors requires a detailed knowledge of the CAN bit synchronization inside a CAN node and interaction of the CAN nodes on the CAN bus.

5.13.6.10.1 Bit Time and Bit Rate

CAN supports bit rates in the range of lower than 1 kBit/s up to 1000 kBit/s. Each member of the CAN network has its own clock generator, usually a quartz oscillator. The timing parameter of the bit time (i.e. the reciprocal of the bit rate) can be configured individually for each CAN node, creating a common bit rate even though the oscillator periods of the CAN nodes (fosc) may be

nuvoton

different.

The frequencies of these oscillators are not absolutely stable, small variations are caused by changes in temperature or voltage and by deteriorating components. As long as the variations remain inside a specific oscillator tolerance range (df), the CAN nodes are able to compensate for the different bit rates by re-synchronizing to the bit stream.

According to the CAN specification, the bit time is divided into four segments (see Figure 5-82). The Synchronization Segment, the Propagation Time Segment, the Phase Buffer Segment 1 and the Phase Buffer Segment 2. Each segment consists of a specific, programmable number of time quanta (see Table 5-16). The length of the time quantum (tq), which is the basic time unit of the bit time, is defined by the CAN controller's APB clock fAPB and the BRP bit of the Bit Timing Register (CAN_BTR): tq = BRP / fAPB.

The Synchronization Segment, Sync Seg, is that part of the bit time where edges of the CAN bus level are expected to occur. The distance between an edge that occurs outside of Sync_Seg, and the Sync_Seg is called the phase error of that edge. The Propagation Time Segment, Prop_Seg, is intended to compensate for the physical delay times within the CAN network. The Phase Buffer Segments Phase Seg1 and Phase Seg2 surround the Sample Point. The (Re-)Synchronization Jump Width (SJW) defines how far a re-synchronization may move the Sample Point inside the limits defined by the Phase Buffer Segments to compensate for edge phase errors.

Figure 5-82 Bit Timing

Range	Remark
[1 32]	defines the length of the time quantum tq
1 tq	fixed length, synchronization of bus input to APB clock
[1 8] tq	compensates for the physical delay times
[18] tq	may be lengthened temporarily by synchronization
[1 8] tq	may be shortened temporarily by synchronization
[1 4] tq	may not be longer than either Phase Buffer Segment
	[1 32] 1 tq [1 8] tq [18] tq [18] tq

Table 5-16 CAN Bit Time Parameters

A given bit rate may be met by different bit time configurations, but for the proper function of the CAN network the physical delay times and the oscillator's tolerance range have to be considered.

5.13.6.10.2 Propagation Time Segment

This part of the bit time is used to compensate physical delay times within the network. These delay times consist of the signal propagation time on the bus and the internal delay time of the CAN nodes.

Any CAN node synchronized to the bit stream on the CAN bus will be out of phase with the transmitter of that bit stream, caused by the signal propagation time between the two nodes. The CAN protocol's non-destructive bitwise arbitration and the dominant acknowledge bit provided by receivers of CAN messages requires that a CAN node transmitting a bit stream must also be able to receive dominant bits transmitted by other CAN nodes that are synchronized to that bit stream. The example in Figure 5-83 shows the phase shift and propagation times between two CAN nodes.

nuvoTon

Figure 5-83 Propagation Time Segment

In this example, both nodes A and B are transmitters, performing an arbitration for the CAN bus. Node A has sent its Start of Frame bit less than one bit time earlier than node B, therefore node B has synchronized itself to the received edge from recessive to dominant. Since node B has received this edge delay (A_to_B) after it has been transmitted, B's bit timing segments are shifted with respect to A. Node B sends an identifier with higher priority and so it will win the arbitration at a specific identifier bit when it transmits a dominant bit while node A transmits a recessive bit. The dominant bit transmitted by node B will arrive at node A after the delay (B_to_A).

Due to oscillator tolerances, the actual position of node A's Sample Point can be anywhere inside the nominal range of node A's Phase Buffer Segments, so the bit transmitted by node B must arrive at node A before the start of Phase_Seg1. This condition defines the length of Prop_Seg.

If the edge from recessive to dominant transmitted by node B arrives at node A after the start of Phase_Seg1, it can happen that node A samples a recessive bit instead of a dominant bit, resulting in a bit error and the destruction of the current frame by an error flag.

The error occurs only when two nodes arbitrate for the CAN bus that have oscillators of opposite ends of the tolerance range and that are separated by a long bus line. This is an example of a minor error in the bit timing configuration (Prop_Seg to short) that causes sporadic bus errors.

Some CAN implementations provide an optional 3 Sample Mode but the C_CAN does not. In this mode, the CAN bus input signal passes a digital low-pass filter, using three samples and a majority logic to determine the valid bit value. This results in an additional input delay of 1 tq, requiring a longer Prop_Seg.

5.13.6.10.3 Phase Buffer Segments and Synchronization

The Phase Buffer Segments (Phase_Seg1 and Phase_Seg2) and the Synchronization Jump Width (SJW) are used to compensate for the oscillator tolerance. The Phase Buffer Segments may be lengthened or shortened by synchronization.

Synchronizations occur on edges from recessive to dominant, their purpose is to control the distance between edges and Sample Points.

Edges are detected by sampling the actual bus level in each time quantum and comparing it with the bus level at the previous Sample Point. A synchronization may be done only if a recessive bit was sampled at the previous Sample Point and if the bus level at the actual time quantum is dominant.

An edge is synchronous if it occurs inside of Sync_Seg, otherwise the distance between edge and the end of Sync_Seg is the edge phase error, measured in time quanta. If the edge occurs before Sync_Seg, the phase error is negative, else it is positive.

Two types of synchronization exist, Hard Synchronization and Re-synchronization.

A Hard Synchronization is done once at the start of a frame and inside a frame only when Resynchronizations occur.

• Hard Synchronization

After a hard synchronization, the bit time is restarted with the end of Sync_Seg, regardless of the edge phase error. Thus hard synchronization forces the edge, which has caused the hard synchronization to lie within the synchronization segment of the restarted bit time.

• Bit Re-synchronization

Re-synchronization leads to a shortening or lengthening of the bit time such that the position of the sample point is shifted with regard to the edge.

When the phase error of the edge which causes Re-synchronization is positive, Phase_Seg1 is lengthened. If the magnitude of the phase error is less than SJW, Phase_Seg1 is lengthened by the magnitude of the phase error, else it is lengthened by SJW.

When the phase error of the edge, which causes Re-synchronization is negative, Phase_Seg2 is shortened. If the magnitude of the phase error is less than SJW, Phase_Seg2 is shortened by the magnitude of the phase error, else it is shortened by SJW.

When the magnitude of the phase error of the edge is less than or equal to the programmed value of SJW, the results of Hard Synchronization and Re-synchronization are the same. If the magnitude of the phase error is larger than SJW, the Re-synchronization cannot compensate the phase error completely, an error (phase error - SJW) remains.

Only one synchronization may be done between two Sample Points. The Synchronizations maintain a minimum distance between edges and Sample Points, giving the bus level time to stabilize and filtering out spikes that are shorter than (Prop_Seg + Phase_Seg1).

Apart from noise spikes, most synchronizations are caused by arbitration. All nodes synchronize "hard" on the edge transmitted by the "leading" transceiver that started transmitting first, but due to propagation delay times, they cannot become ideally synchronized. The "leading" transmitter does not necessarily win the arbitration, therefore the receivers have to synchronize themselves to different transmitters that subsequently "take the lead" and that are differently synchronized to the previously "leading" transmitter. The same happens at the acknowledge field, where the transmitter and some of the receivers will have to synchronize to that receiver that "takes the lead" in the transmission of the dominant acknowledge bit.

Synchronizations after the end of the arbitration will be caused by oscillator tolerance, when the differences in the oscillator's clock periods of transmitter and receivers sum up during the time between synchronizations (at most ten bits). These summarized differences may not be longer than the SJW, limiting the oscillator's tolerance range.

nuvoTon

The examples in Figure 5-84 show how the Phase Buffer Segments are used to compensate for phase errors. There are three drawings of each two consecutive bit timings. The upper drawing shows the synchronization on a "late" edge, the lower drawing shows the synchronization on an "early" edge, and the middle drawing is the reference without synchronization.

Figure 5-84 Synchronization on "late" and "early" Edges

In the first example an edge from recessive to dominant occurs at the end of Prop_Seg. The edge is "late" since it occurs after the Sync_Seg. Reacting to the "late" edge, Phase_Seg1 is lengthened so that the distance from the edge to the Sample Point is the same as it would have been from the Sync_Seg to the Sample Point if no edge had occurred. The phase error of this "late" edge is less than SJW, so it is fully compensated and the edge from dominant to recessive at the end of the bit, which is one nominal bit time long, occurs in the Sync_Seg.

In the second example an edge from recessive to dominant occurs during Phase_Seg2. The edge is "early" since it occurs before a Sync_Seg. Reacting to the "early" edge, Phase_Seg2 is shortened and Sync_Seg is omitted, so that the distance from the edge to the Sample Point is the same as it would have been from an Sync_Seg to the Sample Point if no edge had occurred. As in the previous example, the magnitude of this "early" edge's phase error is less than SJW, so it is fully compensated.

The Phase Buffer Segments are lengthened or shortened temporarily only; at the next bit time, the segments return to their nominal programmed values.

In these examples, the bit timing is seen from the point of view of the CAN implementation's state machine, where the bit time starts and ends at the Sample Points. The state machine omits Sync_Seg when synchronising on an "early" edge because it cannot subsequently redefine that time quantum of Phase_Seg2 where the edge occurs to be the Sync_Seg.

The examples in Figure 5-85 show how short dominant noise spikes are filtered by synchronisations. In both examples the spike starts at the end of Prop_Seg and has the length of (Prop_Seg + Phase_Seg1).

In the first example, the Synchronisation Jump Width is greater than or equal to the phase error of the spike's edge from recessive to dominant. Therefore the Sample Point is shifted after the end of the spike; a recessive bus level is sampled.

nuvoTon

In the second example, SJW is shorter than the phase error, so the Sample Point cannot be shifted far enough; the dominant spike is sampled as actual bus level.

Figure 5-85 Filtering of Short Dominant Spikes

5.13.6.10.4 Oscillator Tolerance Range

The oscillator tolerance range was increased when the CAN protocol was developed from version 1.1 to version 1.2 (version 1.0 was never implemented in silicon). The option to synchronize on edges from dominant to recessive became obsolete, only edges from recessive to dominant are considered for synchronization. The protocol update to version 2.0 (A and B) had no influence on the oscillator tolerance.

The tolerance range df for an oscillator frequency fosc around the nominal frequency fnom is:

 $(1 - df) \bullet f_{nom} \le f_{OSC} \le (1 + df) \bullet f_{nom}$

It depends on the proportions of Phase_Seg1, Phase_Seg2, SJW, and the bit time. The maximum tolerance df is the defined by two conditions (both shall be met):

錯誤!物件無法用編輯功能變數代碼來建立。

錯誤!物件無法用編輯功能變數代碼來建立。

Note: These conditions base on the APB cock = f osc.

It has to be considered that SJW may not be larger than the smaller of the Phase Buffer Segments and that the Propagation Time Segment limits that part of the bit time that may be used for the Phase Buffer Segments.

The combination $Prop_Seg = 1$ and $Phase_Seg1 = Phase_Seg2 = SJW = 4$ allows the largest possible oscillator tolerance of 1.58%. This combination with a Propagation Time Segment of only 10% of the bit time is not suitable for short bit times; it can be used for bit rates of up to 125

nuvoTon

kBit/s (bit time = 8 μ s) with a bus length of 40 m.

5.13.6.10.5 Configuring the CAN Protocol Controller

In most CAN implementations and also in the C_CAN, the bit timing configuration is programmed in two register bytes. The sum of Prop_Seg and Phase_Seg1 (as TSEG1) is combined with Phase_Seg2 (as TSEG2) in one byte, SJW and BRP are combined in the other byte.

In these bit timing registers, the four components TSEG1, TSEG2, SJW, and BRP have to be programmed to a numerical value that is one less than its functional value. Therefore, instead of values in the range of [1..n], values in the range of [0..n-1] are programmed. That way, e.g. SJW (functional range of [1..4]) is represented by only two bits.

Therefore the length of the bit time is (programmed values) [TSEG1 + TSEG2 + 3] t_q or (functional values) [Sync_Seg + Prop_Seg + Phase_Seg1 + Phase_Seg2] t_q .

Figure 5-86 Structure of the CAN Core's CAN Protocol Controller

The data in the bit timing registers is the configuration input of the CAN protocol controller. The Baud Rate Prescaler (configured by BRP) defines the length of the time quantum, the basic time unit of the bit time; the Bit Timing Logic (configured by TSEG1, TSEG2, and SJW) defines the number of time quanta in the bit time.

The processing of the bit time, the calculation of the position of the Sample Point, and occasional synchronizations are controlled by the BTL (Bit Timing Logic) state machine, which is evaluated once each time quantum. The rest of the CAN protocol controller, the BSP (Bit Stream Processor) state machine is evaluated once each bit time, at the Sample Point.

The Shift Register sends the messages serially and parallelizes received messages. Its loading and shifting is controlled by the BSP.

The BSP translates messages into frames and vice versa. It generates and discards the enclosing fixed format bits, inserts and extracts stuff bits, calculates and checks the CRC code, performs the error management, and decides which type of synchronization is to be used. It is evaluated at the Sample Point and processes the sampled bus input bit. The time that is needed to calculate the next bit to be sent after the Sample point (e.g. data bit, CRC bit, stuff bit, error flag, or idle) is called the Information Processing Time (IPT).

The IPT is application specific but may not be longer than 2 t_q ; the IPT for the C_CAN is 0 t_q . Its length is the lower limit of the programmed length of Phase_Seg2. In case of a synchronization, Phase_Seg2 may be shortened to a value less than IPT, which does not affect bus timing.

5.13.6.10.6 Calculating Bit Timing Parameters

Usually, the calculation of the bit timing configuration starts with a desired bit rate or bit time. The resulting bit time (1/bit rate) must be an integer multiple of the APB clock period.

The bit time may consist of 4 to 25 time quanta, the length of the time quantum t_q is defined by the Baud Rate Prescaler with $t_q = (Baud Rate Prescaler)/f_{apb_clk}$. Several combinations may lead to the desired bit time, allowing iterations of the following steps.

First part of the bit time to be defined is the Prop_Seg. Its length depends on the delay times measured in the APB clock. A maximum bus length as well as a maximum node delay has to be defined for expandible CAN bus systems. The resulting time for Prop_Seg is converted into time quanta (rounded up to the nearest integer multiple of t_q).

The Sync_Seg is 1 t_q long (fixed), leaving (bit time – Prop_Seg – 1) t_q for the two Phase Buffer Segments. If the number of remaining t_q is even, the Phase Buffer Segments have the same length, Phase_Seg2 = Phase_Seg1, else Phase_Seg2 = Phase_Seg1 + 1.

The minimum nominal length of Phase_Seg2 has to be regarded as well. Phase_Seg2 may not be shorter than the IPT of the CAN controller, which, depending on the actual implementation, is in the range of [0..2] $t_{\rm q}$.

The length of the Synchronization Jump Width is set to its maximum value, which is the minimum of 4 and Phase_Seg1.

The oscillator tolerance range necessary for the resulting configuration is calculated by the formulas given in Section 5.13.6.10.4: Oscillator Tolerance Range

If more than one configuration is possible, that configuration allowing the highest oscillator tolerance range should be chosen.

CAN nodes with different system clocks require different configurations to come to the same bit rate. The calculation of the propagation time in the CAN network, based on the nodes with the longest delay times, is done once for the whole network.

The oscillator tolerance range of the CAN systems is limited by that node with the lowest tolerance range.

The calculation may show that bus length or bit rate have to be decreased or that the stability of the oscillator frequency has to be increased in order to find a protocol compliant configuration of the CAN bit timing. The resulting configuration is written into the Bit Timing Register: (Phase_Seg2-1) & (Phase_Seg1+Prop_Seg-1) & (SynchronisationJumpWidth-1)&(Prescaler-1)

Example for Bit Timing at High Baud rate

In this example, the frequency of APB_CLK is 10 MHz, BRP is 0, the bit rate is 1 MBit/s.

Τ _q	100	ns	= t _{APB_CLK}
delay of bus driver	50	ns	
delay of receiver circuit	30	ns	
delay of bus line (40m)	220	ns	
t _{Prop}	600	ns	$= 6 \cdot t_q$
t _{SJW}	100	ns	$= 1 \cdot t_q$
t _{TSeg1}	700	ns	$= t_{Prop} + t_{SJW}$
t _{TSeg2}	200	ns	= Information Processing Time + $1 \cdot t_q$
tSync-Seg	100	ns	= 1 • tq
bit time	1000	ns	= t _{Sync-Seg} + t _{TSeg1} + t _{TSeg2}
tolerance for APB_CLK	0.39	%	$=\frac{Min(PB1, PB2)}{2 \times 13 \times (bit \ time - PB2))}$

錯誤!物件無法用編輯功能變數代碼來建立。

In this example ,the concatenated bit time parameters are $(2-1)_3 \& (7-1)_4 \& (1-1)_2 \& (1-1)_6$, the Bit Timing Register is programmed to= 0x1600.

Example for Bit Timing at Low Baudrate

In this example, the frequency of APB_CLK is 2 MHz, BRP is 1, the bit rate is 100 KBit/s.

tq	1	$\mu s = 2 \cdot t_{APB_CLK}$
delay of bus driver	200	ns
delay of receiver circuit	80	ns
delay of bus line (40m)	220	ns
t _{Prop}	1	$\mu s = 1 \bullet t_q$
^t SJW	4	$\mu s = 4 \cdot t_q$
t _{TSeg1}	5	μ s = t _{Prop} + t _{SJW}
t _{TSeg2}	4	$\mu s = Information Processing Time + 3 \cdot t_q$
^t Sync-Seg	1	$\mu s = 1 \bullet t_q$
bit time	10	$\mu s = t_{Sync-Seg} + t_{TSeg1} + t_{TSeg2}$
tolerance for APB_CLK	1.58	$\% = \frac{Min(PB1, PB2)}{2 \times 13 \times (bit \ time - PB2))}$
		錯誤!物件無法用編輯功能變數代碼來建立。

In this example, the concatenated bit time parameters are $(4-1)_3 \& (5-1)_4 \& (4-1)_2 \& (2-1)_6$, the Bit Timing Register is programmed to= 0x34C1.

5.13.7 Register Description

The C_CAN allocates an address space of 256 bytes. The registers are organized as 16-bit registers.

The two sets of interface registers (IF1 and IF2) control the software access to the Message RAM. They buffer the data to be transferred to and from the RAM, avoiding conflicts between software accesses and message reception/transmission.

3. An/Bn: The two sets of data registers – A1, A2 and B1, B2.

5.13.9 CAN Interface Reset State

After the hardware reset, the C_CAN registers hold the reset values given in the register Description in <u>CAN register map</u>.

Additionally the *busoff* state is reset and the output CAN_TX is set to recessive (HIGH). The value 0x0001 (Init = '1') in the CAN Control Register enables the software initialization. The C_CAN does not influence the CAN bus until the application software resets the Init bit to '0'.

The data stored in the Message RAM is not affected by a hardware reset. After powering on, the contents of the Message RAM are undefined.

Test	CCE	DAR	Reserved	EIE	SIE	E	Init

 Bits	Description	
		Reserved
[31:8]	Reserved	There are reserved bits.
		These bits are always read as '0' and must always be written with '0'
		Test Mode Enable
[7]	Test	1 = Test Mode.
		0 = Normal Operation.
		Configuration Change Enable
[6]	CCE	1 = Write access to the Bit Timing Register (CAN_BTIME & CAN_BRP) allowed. (while Init bit =1).
		0 = No write access to the Bit Timing Register.
6		Disable Automatic Re-transmission
[5]	DAR	1 = Automatic Retransmission disabled.
Y at		0 = Automatic Retransmission of disturbed messages enabled.
2	Decembed	Reserved
[4]	Reserved	This is a reserved bit. This bit is always read as '0' and must always be written with '0'.
NG3		Error Interrupt Enable
[3]	EIE	1 = Enabled - A change in the bits BOff or EWarn in the Status Register will generate an interrupt.
	N S	0 = Disabled - No Error Status Interrupt will be generated.
	age -	Status Change Interrupt Enable
[2]	SIE	1 = Enabled - An interrupt will be generated when a message transfer is successfully completed or a CAN bus error is detected.
		0 = Disabled - No Status Change Interrupt will be generated.
[1]	IE	Module Interrupt Enable

		1 = Enabled.
		0 = Disabled.
		Init Initialization
[0]	Init	1 = Initialization is started.
		0 = Normal Operation.

Note: The busoff recovery sequence (see CAN Specification Rev. 2.0) cannot be shortened by setting or resetting the Init bit. If the device goes in the busoff state, it will set Init of its own accord, stopping all bus activities. Once Init has been cleared by the CPU, the device will then wait for 129 occurrences of Bus Idle (129 * 11 consecutive recessive bits) before resuming normal operations. At the end of the busoff recovery sequence, the Error Management Counters will be reset.

During the waiting time after resetting Init, each time a sequence of 11 recessive bits has been monitored, a Bit0Error code is written to the Status Register, enabling the CPU to readily check up whether the CAN bus is stuck at dominant or continuously disturbed and to monitor the proceeding of the busoff recovery sequence.

CAN Status Register (CAN_STATUS)

Register	Offset	R/W	Description	Reset Value
CAN_STATUS	CAN0_BA+0x04	R/W	CAN Status Register	0x0000_0000

				V/AL N

7	6	5	4	3	2	1	0
BOFF	EWarn	EPass	RxOK	TxOK		LEC	5

Bits	Description	
[31:8]	Reserved	Reserved
[01.0]	Reserved	This is a reserved bit. This bit is always read as '0' and must always be written with '0'.
		Busoff Status (Read Only)
[7]	BOff	1 = The CAN module is in busoff state.
		0 = The CAN module is not in busoff state.
		Error Warning Status (Read Only)
[6]	EWarn	1 = At least one of the error counters in the EML has reached the error warning limit of 96.
		0 = Both error counters are below the error warning limit of 96.
		Error Passive (Read Only)
[5]	EPass	1 = The CAN Core is in the error passive state as defined in the CAN Specification.
		0 = The CAN Core is error active.
		Received a Message Successfully
[4]	RxOK	1 = A message has been successfully received since this bit was last reset by the CPU (independent of the result of acceptance filtering).
S.	ets.	0 = No message has been successfully received since this bit was last reset by the CPU. This bit is never reset by the CAN Core.
NG5	The second	Transmitted a Message Successfully
[3]	ТхОК	1 = Since this bit was last reset by the CPU, a message has been successfully (error free and acknowledged by at least one other node) transmitted.
	KA	0 = Since this bit was reset by the CPU, no message has been successfully transmitted. This bit is never reset by the CAN Core.
	62	Last Error Code (Type of the last error to occur on the CAN bus)
[2:0]	LEC	The LEC field holds a code, which indicates the type of the last error to occur on the CAN bus. This field will be cleared to '0' when a message has been transferred (reception or transmission) without error. The unused code '7' may be written by the CPU to check for updates. Table 5-18 describes the error codes.

Error Code	Meanings
0	No Error
1	Stuff Error: More than 5 equal bits in a sequence have occurred in a part of a received message where this is not allowed.
2	Form Error: A fixed format part of a received frame has the wrong format.
3	AckError: The message this CAN Core transmitted was not acknowledged by another node.
4	Bit1Error: During the transmission of a message (with the exception of the arbitration field), the device wanted to send a recessive level (bit of logical value '1'), but the monitored bus value was dominant.
5	Bit0Error: During the transmission of a message (or acknowledge bit, or active error flag, or overload flag), though the device wanted to send a dominant level (data or identifier bit logical value '0'), but the monitored Bus value was recessive. During busoff recovery, this status is set each time a sequence of 11 recessive bits has been monitored. This enables the CPU to monitor the proceedings of the busoff recovery sequence (indicating the bus is not stuck at <i>dominant</i> or continuously disturbed).
6	CRCError: The CRC check sum was incorrect in the message received, the CRC received for an incoming message does not match with the calculated CRC for the received data.
7	Unused: When the LEC shows the value '7', no CAN bus event was detected since the CPU wrote this value to the LEC.

Table 5-18 Error Codes

Status Interrupts

A Status Interrupt is generated by bits **BOff** and **EWarn** (Error Interrupt) or by **RxOk**, **TxOk**, and **LEC** (Status Change Interrupt) assumed that the corresponding enable bits in the CAN Control Register are set. A change of bit **EPass** or a write to **RxOk**, **TxOk**, or **LEC** will never generate a Status Interrupt.

Reading the Status Register will clear the Status Interrupt value (8000h) in the Interrupt Register, if it is pending.

			Intid	15:8]	8	50	The	
7	6	5	4	3	2	1	0	
			Intid	[7:0]		4	ON DA	

Bits	Description	
		Interrupt Identifier (Indicates the source of the interrupt. Ref. Table 5-19)
[15:0]	Intid	If several interrupts are pending, the CAN Interrupt Register will point to the pending interrupt with the highest priority, disregarding their chronological order. An interrupt remains pending until the application software has cleared it. If IntId is different from 0x0000 and IE is set, the IRQ interrupt signal to the EIC is active. The interrupt remains active until IntId is back to value 0x0000 (the cause of the interrupt is reset) or until IE is reset.
		The Status Interrupt has the highest priority. Among the message interrupts, the Message Object's interrupt priority decreases with increasing message number.
		A message interrupt is cleared by clearing the Message Object's IntPnd bit. The Status Interrupt is cleared by reading the Status Register.

Intid Value	Meanings							
0x0000	No Interrupt is Pending							
0x0001-0x0020	Number of Message Object which caused the interrupt.							
0x0021-0x7FFF	Unused							
0x8000	Status Interrupt							
0x8001-0xFFFF Unused

Bits	Description	
		Reserved
[31:4]	Reserved	There are reserved bits. These bits are always read as '0' and must always be written with '0'.
		BRPE: Baud Rate Prescaler Extension
[3:0]	BRPE	0x00-0x0F: By programming BRPE , the Baud Rate Prescaler can be extended to values up to 1023. The actual interpretation by the hardware is that one more than the value programmed by BRPE (MSBs) and BTIME (LSBs) is used.

Message Interface Register Sets

There are two sets of Interface Registers, which are used to control the CPU access to the Message RAM. The Interface Registers avoid conflict between the CPU accesses to the Message RAM and CAN message reception and transmission by buffering the data to be transferred. A complete Message Object or parts of the Message Object may be transferred between the Message RAM and the IFn Message Buffer registers in one single transfer.

The function of the two interface register sets is identical except for the Basic test mode. They can be used the way one set of registers is used for data transfer to the Message RAM while the other set of registers is used for the data transfer from the Message RAM, allowing both processes to be interrupted by each other. Table 5-20 (IF1 and IF2 Message Interface Register Set) provides an overview of the two Interface Register sets.

Each set of Interface Registers consists of Message Buffer Registers controlled by their own Command Registers. The Command Mask Register specifies the direction of the data transfer and which parts of a Message Object will be transferred. The Command Request Register is used to select a Message Object in the Message RAM as target or source for the transfer and to start the action specified in the Command Mask Register.

Address	IF1 Register Set	Address	IF2 Register Set

Bits	Description	
		Busy Flag
[15]	Busy	1 = Writing to the IFn Command Request Register is in progress. This bit can only be read by the software.
		0 = Read/write action has finished.
	4:6] Reserved	Reserved
[14:6]		There are reserved bits. These bits are always read as '0' and must always be written with '0'.
		Message Number
		0x01-0x20: Valid Message Number, the Message Object in the Message
[5:0]	0] Message Number	RAM is selected for data transfer.
		0x00: Not a valid Message Number, interpreted as 0x20.
		0x21-0x3F: Not a valid Message Number, interpreted as 0x01-0x1F.

A message transfer is started as soon as the application software has written the message number to the Command Request Register. With this write operation, the Busy bit is automatically set to notify the CPU that a transfer is in progress. After a waiting time of 3 to 6 APB_CLK periods, the transfer between the Interface Register and the Message RAM is completed. The Busy bit is cleared.

Note:When a Message Number that is not valid is written into the Command Request Register, the Message Number will be transformed into a valid value and that Message Object will be transferred.

nuvoton

IFn Command Mask Register (CAN_IFn_CMASK)

The control bits of the IF*n* Command Mask Register specify the transfer direction and select which of the IF*n* Message Buffer Registers are source or target of the data transfer.

Bits	Description				
[31:16]	Reserved	Reserved There are reserved bits. These bits are always read as '0' and must always be written with '0'.			
[15]	NewDat	 New Data 1 = The Message Handler or the application software has written new data into the data portion of this Message Object. 0 = No new data has been written into the data portion of this Message Object by the Message Handler since last time this flag was cleared by the application software. 			
[14]	MsgLst	 Message Lost (only valid for Message Objects with direction = receive) 1 = The Message Handler stored a new message into this object when NewDat was still set, the CPU has lost a message. 0 = No message lost since last time this bit was reset by the CPU. 			
[13]	IntPnd	Interrupt Pending 1 = This message object is the source of an interrupt. The Interrupt Identifier in the Interrupt Register will point to this message object if there is no other interrupt source with highe priority. 0 = This message object is not the source of an interrupt.			
[12]	UMask	Use Acceptance Mask 1 = Use Mask (Msk28-0, MXtd, and MDir) for acceptance filtering. 0 = Mask ignored. Note: If the UMask bit is set to one, the Message Object's mask bits have to be programmed during initialization of the Message Object before MsgVal is set to one.			
[11]	TxIE	Transmit Interrupt Enable 1 = IntPnd will be set after a successful transmission of a frame.			

NuMicro™ NUC130/NUC140 Technical Reference Manual

nuvoTon

		0 = IntPnd will be left unchanged after the successful transmission of a frame.						
		Receive Interrupt Enable						
[10]	RxIE	1 = IntPnd will be set after a successful reception of a frame.						
		0 = IntPnd will be left unchanged after a successful reception of a frame.						
		Remote Enable						
[9]	RmtEn	1 = At the reception of a Remote Frame, TxRqst is set.						
		0 = At the reception of a Remote Frame, TxRqst is left unchanged.						
		Transmit Request						
[8]	TxRqst	1 = The transmission of this Message Object is requested and is not yet done.						
		0 = This Message Object is not waiting for transmission.						
		End of Buffer						
		1 = Single Message Object or last Message Object of a FIFO Buffer.						
[7]	ЕоВ	0 = Message Object belongs to a FIFO Buffer and is not the last Message Object of that FIFO Buffer.						
		Note: This bit is used to concatenate two or more Message Objects (up to 32) to build a FIFO Buffer. For single Message Objects (not belonging to a FIFO Buffer), this bit must always be set to one.						
		Reserved						
[6:4]	Reserved	There are reserved bits. These bits are always read as '0' and must always be written with '0'.						
		Data Length Code						
		0-8: Data Frame has 0-8 data bytes.						
		9-15: Data Frame has 8 data bytes						
		Note: The Data Length Code of a Message Object must be defined the same as in all the corresponding objects with the same identifier at other nodes. When the Message Handler stores a data frame, it will write the DLC to the value given by the received message.						
		Data 0: 1st data byte of a CAN Data Frame						
		Data 1: 2nd data byte of a CAN Data Frame						
		Data 2: 3rd data byte of a CAN Data Frame						
[3:0]	DLC	Data 3: 4th data byte of a CAN Data Frame						
		Data 4: 5th data byte of a CAN Data Frame						
		Data 5: 6th data byte of a CAN Data Frame						
		Data 6: 7th data byte of a CAN Data Frame						
the.		Data 7 : 8th data byte of a CAN Data Frame						
	2	Note: The Data 0 Byte is the first data byte shifted into the shift register of the CAN Core during a reception while the Data 7 byte is the last. When the Message Handler stores a Data Frame, it will write all the eight data bytes into a Message Object. If the Data Length Code is less than 8, the remaining bytes of the Message Object will be overwritten by unspecified values .

Bits	Description	
		Reserved
[31:16]	Reserved	There are reserved bits. These bits are always read as '0' and must always be written with '0'.
[15:8]	Data7	Data byte 7 8th data byte of CAN Data Frame.
[7.0]	Deter	Data byte 6
[7:0]	Data6	7th data byte of CAN Data Frame.

In a CAN Data Frame, Data(0) is the first, Data(7) is the last byte to be transmitted or received. In CAN's serial bit stream, the MSB of each byte will be transmitted first.

Message Object in the Message Memory

There are 32 Message Objects in the Message RAM. To avoid conflicts between application software access to the Message RAM and CAN message reception and transmission, the CPU cannot directly access the Message Objects, these accesses are handled through the IF*n* Interface Registers. Table 5-21 provides an overview of the structures of a Message Object.

								2				
	Message Object											
UMask	Msk [28:0]	MXtd	MDir	EoB	Nev	vDat	MsgLst	RxIE	TxIE	IntPnd	RmtEn	TxRqst
MsgVal	ID [28:0]	Xtd	Dir	DLC [3:0]	Data0	Data1	Data2	Data3	Data4	Data5	Data6	Data7

Table 5-21 Structure of a Message Object in Message Memory

The Arbitration Registers **ID28-0**, **Xtd**, and **Dir** are used to define the identifier and type of outgoing messages and are used (together with the mask registers **Msk28-0**, **MXtd**, and **MDir**) for acceptance filtering of incoming messages. A received message is stored in the valid Message Object with matching identifier and Direction = *receive* (Data Frame) or Direction = *transmit* (Remote Frame). Extended frames can be stored only in Message Objects with **Xtd** = one, standard frames in Message Objects with **Xtd** = zero. If a received message (Data Frame or Remote Frame) matches with more than one valid Message Object, it is stored into that with the lowest message number.

Message Handler Registers

All Message Handler registers are read-only. Their contents (**TxRqst**, **NewDat**, **IntPnd**, and **MsgVal** bits of each Message Object and the Interrupt Identifier) are status information provided by the Message Handler FSM.

Transmission Request Register 1 (CAN_TXREQ1)

These registers hold the **TxRqst** bits of the 32 Message Objects. By reading the **TxRqst** bits, the software can check which Message Object in a Transmission Request is pending. The **TxRqst** bit of a specific Message Object can be set/reset by the application software through the IFn Message Interface Registers or by the Message Handler after reception of a Remote Frame or after a successful transmission.

Register	Offset	R/W	Description	Reset Value

5.14 PS/2 Device Controller (PS2D)

5.14.1 Overview

PS/2 device controller provides basic timing control for PS/2 communication. All communication between the device and the host is managed through the CLK and DATA pins. Unlike PS/2 keyboard or mouse device controller, the received/transmit code needs to be translated as meaningful code by firmware. The device controller generates the CLK signal after receiving a request to send, but host has ultimate control over communication. DATA sent from the host to the device is read on the rising edge and DATA sent from device to the host is change after rising edge. A 16 bytes FIFO is used to reduce CPU intervention. S/W can select 1 to 16 bytes for a continuous transmission.

5.14.2 Features

- Host communication inhibit and request to send detection
- Reception frame error detection
- Programmable 1 to 16 bytes transmit buffer to reduce CPU intervention
- Double buffer for data reception
- S/W override bus

5.14.3 Block Diagram

The PS/2 device controller consists of APB interface and timing control logic for DATA and CLK lines.

Figure 5-87 PS/2 Device Block Diagram

ηυνοτοη

5.14.4 Functional Description

5.14.4.1 Communication

The PS/2 device implements a bidirectional synchronous serial protocol. The bus is "Idle" when both lines are high (open-collector). This is the only state where the device is allowed start to transmit DATA. The host has ultimate control over the bus and may inhibit communication at any time by pulling the CLK line low.

The CLK signal is generated by PS/2 device. If the host wants to send DATA, it must first inhibit communication from the device by pulling CLK low. The host then pulls DATA low and releases CLK. This is the "Request-to-Send" state and signals the device to start generating CLK pulses.

DATA	CLK	Bus State	Ν.
High	High	Idle	1
High	Low	Communication Inhibit	20
Low	High	Host Request to Send	3

All data is transmitted one byte at a time and each byte is sent in a frame consisting of 11 or 12 bits. These bits are:

- 1 start bit. This is always 0
- 8 DATA bits, least significant bit first
- 1 parity bit (odd parity)
- 1 stop bit. This is always 1
- 1 acknowledge bit (host-to-device communication only)

The parity bit is set if there is an even number of 1's in the data bits and cleared to 0 if there is an odd number of 1's in the data bits. The number of 1's in the data bits plus the parity bit always add up to an odd number set to 1. This is used for error detection. The device must check this bit and if incorrect it should respond as if it had received an invalid command.

The host may inhibit communication at any time by pulling the CLK line low for at least 100 microseconds. If a transmission is inhibited before the 11th clock pulse, the device must abort the current transmission and prepare to retransmit the current data when host releases Clock. In order to reserve enough time for s/w to decode host command, the transmit logic is blocked by RXINT bit, S/W must clear RXINT bit to start retransmit. S/W can write CLRFIFO to 1 to reset FIFO pointer if need.

Device-to-Host

The device uses a serial protocol with 11-bit frames. These bits are:

- 1 start bit. This is always 0
- 8 DATA bits, least significant bit first
- 1 parity bit (odd parity)
- 1 stop bit. This is always 1

The device writes a bit on the DATA line when CLK is high, and it is read by the host when CLK is low. Figure 5-88 in the following illustrate this.

Figure 5-88 Data Format of Device-to-Host

Host-to-Device:

First of all, the PS/2 device always generates the CLK signal. If the host wants to send DATA, it must first put the CLK and DATA lines in a "Request-to-send" state as follows:

- Inhibit communication by pulling CLK low for at least 100 microseconds
- Apply "Request-to-send" by pulling DATA low, then release CLK

The device should check for this state at intervals not to exceed 10 milliseconds. When the device detects this state, it will begin generating CLK signals and CLK in eight DATA bits and one stop bit. The host changes the DATA line only when the CLK line is low, and DATA is read by the device when CLK is high.

After the stop bit is received, the device will acknowledge the received byte by bringing the DATA line low and generating one last CLK pulse. If the host does not release the DATA line after the 11th CLK pulse, the device will continue to generate CLK pulses until the DATA line is released.

Figure 5-89 Data Format of Host-to-Device

The host and the device DATA and CLK detailed timing for communication is shown below.

5.14.4.2 PS/2 Bus Timing Specification

Figure 5-91 PS/2 Bus Timing

Symbol	Timing Parameter	MIN.	Max
T1	DATA transition to the falling edge of CLK	5us	25us
T2	Rising edge of CLK to DATA transition	5us	T4-5us
T3	Duration of CLK inactive	30us	50us
T4	Duration of CLK active	30us	50us
T5	Time to auxiliary device inhibit after 11 th clock to ensure auxiliary device does not start another transmission	>0	50us
Τ7	Duration of CLK inactive	30us	50us
Т8	Duration of CLK active	30us	50us
Т9	Time from inactive to active CLK transition, use to time auxiliary device sample DATA	5us	25us

5.14.4.3 TX FIFO Operation

Writing PS2TXDATA0 register starts device to host communication. S/W is required to define TXFIFO depth before writing transmission data to TX FIFO. 1st START bit is sent to PS/2 bus 100us after S/W writes TX FIFO, if there is more than 4 bytes data need to be sent, S/W can write residual data to PS2TXDATA1-3 before 4th byte transmit complete. A time delay 100us is added between two consecutive bytes.

		Receive Interrupt
		This bit is set to 1 when acknowledge bit is sent for Host to device communication Interrupt occurs if RXINTEN bit is set to 1.
[0]	RXINT	1 = Receive interrupt occurs
5.		0 = No interrupt
SP4		Write 1 to clear this bit to 0.

5.15 I²S Controller (I²S)

5.15.1 Overview

The I²S controller consists of IIS protocol to interface with external audio CODEC. Two 8 word deep FIFO for read path and write path respectively and is capable of handling 8 ~ 32 bit word sizes. DMA controller handles the data movement between FIFO and memory.

5.15.2 Features

- Operated as either master or slave
- Capable of handling 8-, 16-, 24- and 32-bit word sizes
- Mono and stereo audio data supported
- I²S and MSB justified data format supported
- Two 8 word FIFO data buffers are provided, one for transmit and one for receive
- Generates interrupt requests when buffer levels cross a programmable boundary
- Two DMA requests one for transmitting and one for receiving

Bits	Description	Description				
[31:22]	Reserved	Reserved				
		Enable Receive DMA				
[21]	RXDMA	When RX DMA is enabled, $I^2S$ requests DMA to transfer data from receive FIFO to SRAM if FIFO is not empty.				
		1 = RX DMA Enabled				
		0 = RX DMA Disabled				
		Enable Transmit DMA				
[20]	TXDMA	When TX DMA is enables, $I^2S$ request DMA to transfer data from SRAM to transmit FIFO if FIFO is not full.				
		1 = TX DMA Enabled				
S		0 = TX DMA Disabled				
2 Testy		Clear Receive FIFO				
[19]	CLR_RXFIFO	Write 1 to clear receive FIFO, internal pointer is reset to FIFO start point, and RXFIFO_LEVEL[3:0] returns to zero and receive FIFO becomes empty.				
"Gy		This bit is cleared by hardware automatically, read it return 0.				
00	220	Clear Transmit FIFO				
[18]	CLR_TXFIFO	Write 1 to clear transmit FIFO, internal pointer is reset to FIFO start point, and TXFIFO_LEVEL[3:0] returns to zero and transmit FIFO becomes empty but data in transmit FIFO is not changed.				
	20 65	This bit is clear by hardware automatically, read it return 0.				

		Left Channel Zero-cross Detection Enable			
[17]	LCHZCEN	If this bit is set to 1, when left channel data sign bit change or next shift data bits are a zero then LZCF flag in I2SSTATUS register is set to 1.			
[17]	ECHZCEN	1 = Left channel zero cross detection Enabled			
		0 = Left channel zero cross detection Disabled			
		Right Channel Zero-cross Detection Enable			
[16]	RCHZCEN	If this bit is set to 1, when right channel data sign bit change or next shift data bits are all zero then RZCF flag in I2SSTATUS register is set to 1.			
		1 = Right channel zero cross detection Enabled			
		0 = Right channel zero cross detection Disabled			
		Master Vlock Enable			
[15]	MCLKEN	In the NuMicro™ NUC100 series, external crystal clock is frequency 2*N*256fs software can program MCLK_DIV[2:0] in I2SCLKDIV register to get 256fs clock to audio codec chip.			
		1 = Master clock Enabled			
		0 = Master clock Disabled			
		Receive FIFO Threshold Level			
	RXTH	When received data word(s) in buffer is equal or higher than threshold level the RXTHF flag is set.			
		000 = 1 word data in receive FIFO			
		001 = 2 word data in receive FIFO			
[14:12]		010 = 3 word data in receive FIFO			
		011 = 4 word data in receive FIFO			
		100 = 5 word data in receive FIFO			
		101 = 6 word data in receive FIFO			
		110 = 7 word data in receive FIFO			
		111 = 8 word data in receive FIFO			
		Transmit FIFO threshold level			
		If remain data word (32 bits) in transmit FIFO is the same or less than threshold leve then TXTHF flag is set.			
		000 = 0 word data in transmit FIFO			
SP		001 = 1 word data in transmit FIFO			
[11:9]	тхтн	010 = 2 words data in transmit FIFO			
[11:0]		011 = 3 words data in transmit FIFO			
	100	100 = 4 words data in transmit FIFO			
592	Ta	101 = 5 words data in transmit FIFO			
0	200	110 = 6 words data in transmit FIFO			
5	in Co.	111 = 7 words data in transmit FIFO			

		Slave mode
[8]	SLAVE	I ² S can operate as master or slave. For Master mode, I2S_BCLK and I2S_LRCLK pins are output mode and send bit clock from NuMicro™ NUC100 series to Audio CODEC chip. In Slave mode, I2S_BCLK and I2S_LRCLK pins are input mode and I2S_BCLK and I2S_LRCLK signals are received from outer Audio CODEC chip.
		1 = Slave mode
		0 = Master mode
		Data format
[7]	FORMAT	1 = MSB justified data format
		0 = I ² S data format
		Monaural Data
		1 = Data is monaural format
[6]	MONO	0 = Data is stereo format
		Note: when chip records data, only right channel data will be saved if monaural format is selected.
		Word Width
		00 = data is 8-bit
[5:4]	WORDWIDTH	01 = data is 16-bit
		10 = data is 24-bit
		11 = data is 32-bit
		Transmit Mute Enable
[3]	MUTE	1= Transmit channel zero
		0 = Transmit data is shifted from buffer
		Receive Enable
[2]	RXEN	1 = Data receiving Enabled
		0 = Data receiving Disabled
		Transmit Enable
[1]	TXEN	1 = Data transmit Enabled
		0 = Data transmit Disabled

Bits	Description	
		Receive FIFO register
[31:0]		I ² S contains 8 words (8x32 bit) data buffer for data receive. Read this register to get data in FIFO. The remaining data word number is indicated by RX_LEVEL[3:0] in I2SSTATUS register.

OTM NUC130/NUC140 TECHNICAL REFERENCE MANUA

#### 5.16 Analog-to-Digital Converter (ADC)

#### 5.16.1 Overview

The NuMicro[™] NUC100 Series contains one 12-bit successive approximation analog-to-digital converters (SAR A/D converter) with 8 input channels. The A/D converter supports three operation modes: single, single-cycle scan and continuous scan mode. The A/D converters can be started by software and external STADC pin.

#### 5.16.2 Features

- Analog input voltage range: 0~V_{REF}
- 12-bit resolution and 10-bit accuracy is guaranteed
- Up to 8 single-end analog input channels or 4 differential analog input channels
- Maximum ADC clock frequency is 16 MHz
- Up to 700K SPS conversion rate
- Three operating modes
  - Single mode: A/D conversion is performed one time on a specified channel
  - Single-cycle scan mode: A/D conversion is performed one cycle on all specified channels with the sequence from the lowest numbered channel to the highest numbered channel
  - Continuous scan mode: A/D converter continuously performs Single-cycle scan mode until software stops A/D conversion
- An A/D conversion can be started by
  - Software write 1 to ADST bit
  - External pin STADC
- Conversion results are held in data registers for each channel with valid and overrun indicators
- Conversion result can be compared with specify value and user can select whether to generate an interrupt when conversion result is equal to the compare register setting
- Channel 7 supports 3 input sources: external analog voltage, internal band-gap voltage, and internal temperature sensor output
- Support Self-calibration to minimize conversion error

### nuvoTon

### 5.16.3 Block Diagram

Figure 5-98 ADC Controller Block Diagram
### 5.16.4 Functional Description

The A/D converter operates by successive approximation with 12-bit resolution. This A/D converter is equipped with self-calibration function to minimize conversion error, user can write 1 to CALEN bit in ADCALR register to enable calibration function, while internal calibration is finished the CAL_DONE bit will be set to 1 by hardware. The ADC has three operation modes: single mode, single-cycle scan mode and continuous scan mode. When changing the operating mode or analog input channel, in order to prevent incorrect operation, software must clear ADST bit to 0 in ADCR register.

#### 5.16.4.1 Self-Calibration

When chip power on or switch ADC input type between single-end input and differential input, it needs to do ADC self-calibration to minimize the conversion error. User can write 1 to CALEN bit of ADCALR register to start the self-calibration. It needs 127 ADC clocks to complete the calibration and the CAL_DONE bit will be set to 1 by hardware. The detail timing is shown below.

Figure 5-99 ADC Converter Self-Calibration Timing Diagram

#### 5.16.4.2 ADC Clock Generator

The maximum sampling rate is up to 700K SPS. The ADC engine has four clock sources selected by 2-bit ADC_S (CLKSEL1[3:2]), the ADC clock frequency is divided by an 8-bit prescaler with the formula:

The ADC clock frequency = (ADC clock source frequency) / (ADC_N+1);

where the 8-bit ADC_N is located in register CLKDIV[23:16].

If the clock source is from HCLK, the ADC_N cannot be 0.

### NuMicro™ NUC130/NUC140 Technical Reference Manual

# nuvoTon

Figure 5-100 ADC Clock Control

#### 5.16.4.3 Single Mode

In single mode, A/D conversion is performed only once on the specified single channel. The operations are as follows:

- 1. A/D conversion will be started when the ADST bit of ADCR is set to 1 by software or external trigger input.
- 2. When A/D conversion is finished, the result is stored in the A/D data register corresponding to the channel.
- 3. The ADF bit of ADSR register will be set to 1. If the ADIE bit of ADCR register is set to 1, the ADC interrupt will be asserted.
- 4. The ADST bit remains 1 during A/D conversion. When A/D conversion ends, the ADST bit is automatically cleared to 0 and the A/D converter enters idle state. Note that, after clearing the ADST bit, the ADST bit must be kept at 0 at least one ADC clock period before setting it to 1 again. If not, the A/D converter may not work.

**Note:** If software enables more than one channel in single mode, the channel with the lowest number will be selected and the other enabled channels will be ignored.

Figure 5-101 Single Mode Conversion Timing Diagram

#### 5.16.4.4 Single-Cycle Scan Mode

In single-cycle scan mode, A/D conversion will sample and convert the specified channels once in the sequence from the lowest number enabled channel to the highest number enabled channel.

- 1. When the ADST bit of ADCR is set to 1 by software or external trigger input, A/D conversion starts on the channel with the lowest number.
- 2. When A/D conversion for each enabled channel is completed, the result is sequentially transferred to the A/D data register corresponding to each channel.
- 3. When the conversions of all the enabled channels are completed, the ADF bit in ADSR is set to 1. If the ADC interrupt function is enabled, the ADC interrupt occurs.
- 4. After A/D conversion ends, the ADST bit is automatically cleared to 0 and the A/D converter enters idle state. If ADST is cleared to 0 before all enabled ADC channels conversion done, ADC controller will finish current conversion and the result of the lowest enabled ADC channel will become unpredictable. Note that, after clearing the ADST bit to 0, the ADST bit must be kept at 0 at least one ADC clock period before setting it to 1 again. If not, the A/D converter may not work.

An example timing diagram for single-cycle scan on enabled channels (0, 2, 3 and 7) is shown below.

		le-cycle scan on channel 0, 2, 3 and 7 (ADCHER[7:0] = $0x10001101b$ )

Figure 5-102 Single-Cycle Scan on Enabled Channels Timing Diagram

#### 5.16.4.5 Continuous Scan Mode

In continuous scan mode, A/D conversion is performed sequentially on the specified channels that enabled by CHEN bits in ADCHER register (maximum 8 channels for ADC). The operations are as follows:

- 1. When the ADST bit in ADCR is set to 1 by software or external trigger input, A/D conversion starts on the channel with the lowest number.
- 2. When A/D conversion for each enabled channel is completed, the result of each enabled channel is stored in the A/D data register corresponding to each enabled channel.
- 3. When A/D converter completes the conversions of all enabled channels sequentially, the ADF bit (ADSR[0]) will be set to 1. If the ADC interrupt function is enabled, the ADC interrupt occurs. The conversion of the enabled channel with the lowest number will start again if software has not cleared the ADST bit.
- 4. As long as the ADST bit remains at 1, the step 2 ~ 3 will be repeated. When ADST is cleared to 0, ADC controller will finish current conversion and the result of the lowest enabled ADC channel will become unpredictable.

An example timing diagram for continuous scan on enabled channels (0, 2, 3 and 7) is shown below:

00
101b)
-

#### 5.16.4.6 External trigger Input Sampling and A/D Conversion Time

In single-cycle scan mode, A/D conversion can be triggered by external pin request. When the ADCR.TRGEN is set to high to enable ADC external trigger function, setting the TRGS[1:0] bits to 00b is to select external trigger input from the STADC pin. Software can set TRGCOND[1:0] to select trigger condition is falling/rising edge or low/high level. If level trigger condition is selected, the STADC pin must be kept at defined state at least 8 PCLKs. The ADST bit will be set to 1 at the 9th PCLK and start to conversion. Conversion is continuous if external trigger input is kept at

active state in level trigger mode. It is stopped only when external condition trigger condition disappears. If edge trigger condition is selected, the high and low state must be kept at least 4 PLCKs. Pulse that is shorter than this specification will be ignored.

#### 5.16.4.7 Conversion Result Monitor by Compare Function

ADC controller provide two sets of compare register ADCMPR0 and ADCMPR1, to monitor maximum two specified channels conversion result from A/D conversion controller, refer to Figure 5-104. Software can select which channel to be monitored by set CMPCH(ADCMPRx[5:0]) and CMPCOND bit is used to check conversion result is less than specify value or greater than (equal to) value specified in CMPD[11:0]. When the conversion of the channel specified by CMPCH is completed, the comparing action will be triggered one time automatically. When the compare result meets the setting, compare match counter will increase 1, otherwise, the compare match counter will be clear to 0. When counter value reach the setting of (CMPMATCNT+1) then CMPF bit will be set to 1, if CMPIE bit is set then an ADC_INT interrupt request is generated. Software can use it to monitor the external analog input pin voltage transition in scan mode without imposing a load on software. Detail logics diagram is shown below.

Figure 5-104 A/D Conversion Result Monitor Logics Diagram

#### 5.16.4.8 Interrupt Sources

There are three interrupt sources of ADC interrupt. When an ADC operation mode finishes its conversion, the A/D conversion end flag, ADF, will be set to 1. The CMPF0 and CMPF1 are the compare flags of compare function. When the conversion result meets the settings of ADCMPR0/1, the corresponding flag will be set to 1. When one of the flags, ADF, CMPF0 and CMPF1, is set to 1 and the corresponding interrupt enable bit, ADIE of ADCR and CMPIE of ADCMPR0/1, is set to 1, the ADC interrupt will be asserted. Software can clear the flag to revoke the interrupt request.

Figure 5-105 A/D Controller Interrupt

#### 5.16.4.9 Peripheral DMA Request

When A/D conversion is finished, the conversion result will be loaded into ADDR register and VALID bit will be set to 1. If the PTEN bit of ADCR is set, ADC controller will generate a request to PDMA. User can use PDMA to transfer the conversion results to a user-specified memory space without CPU's intervention. The source address of PDMA operation is fixed at ADPDMA, no matter what channels was selected. When PDMA is transferring the conversion result, ADC will continue converting the next selected channel if the ADC operation mode is Single Scan mode or Continuous Scan mode. User can monitor current PDMA transfer data through reading ADPDMA register. If ADC completes the conversion of a selected channel and the last conversion result of the same channel has not been transferred by PDMA, OVERUN bit of the corresponding channel will be set and the last ADC conversion result will be overwrite by the new ADC conversion result. PDMA will transfer the latest data of selected channels to the user-specified destination address.

Bits	Description	
[31:2]	Reserved	Reserved
		Calibration Complete
		1 = A/D converter self-calibration is finished.
[1]	CALDONE	0 = A/D converter has not been calibrated or calibration is in progress if the CALEN b is set.
		When writing 0 to the CALEN bit, CALDONE bit is cleared by hardware immediately. This bit is read only.
		Self-calibration Enable
		1 = Self-calibration Enabled
[0]	CALEN	0 = Self-calibration Disabled
		Software can set this bit to 1 to enable A/D converter to do self-calibration function. It needs 127 ADC clocks to complete calibration. This bit must be kept at 1 after CALDONE asserted. Clearing this bit will disable self-calibration function.

### 5.17 Analog Comparator (CMP)

#### 5.17.1 Overview

The NuMicro[™] NUC100 Series contains two comparators, which can be used in a number of different configurations. The comparator output is a logical one when positive input greater than negative input, otherwise the output is a zero. Each comparator can be configured to cause an interrupt when the comparator output value changes. The block diagram is shown in Figure 5-108.

### 5.17.2 Features

- Analog input voltage range: 0~5.0 V
- Hysteresis function supported
- Two analog comparators with optional internal reference voltage input at negative end
- One interrupt vector for both comparators

### 5.17.3 Block Diagram

### NuMicro™ NUC130/NUC140 Technical Reference Manual

## nuvoTon

Figure 5-108 Analog Comparator Block Diagram

### 5.17.4 Functional Description

#### 5.17.4.1 Interrupt Sources

The output of comparators are sampled by PCLK and reflected at CO1 and CO2 of CMPSR register. If CMP0IE/CMP1IE of CMP0CR/CMP1CR is set to 1, the comparator interrupt will be enabled. As the output state of comparator is changed, the comparator interrupt will be asserted and the corresponding flag, CMPF0 or CMPF1, will be set. Software can clear the flag to 0 by writing 1 to it.

### 5.18 PDMA Controller (PDMA)

#### 5.18.1 Overview

The NuMicro[™] NUC130/NUC140 contains a peripheral direct memory access (PDMA) controller that transfers data to and from memory or transfer data to and from APB devices. The PDMA has nine channels of DMA (Peripheral-to-Memory or Memory-to-Peripheral or Memory-to-Memory). For each PDMA channel (PDMA CH0~CH8), there is one word buffer as transfer buffer between the Peripherals APB devices and Memory.

Software can stop the PDMA operation by disable PDMA [PDMACEN]. The CPU can recognize the completion of a PDMA operation by software polling or when it receives an internal PDMA interrupt. The PDMA controller can increase source or destination address or fixed them as well.

Note: The partial of NuMicro[™] NUC130/NUC140 only has 1 PDMA channel (channel 0).

#### 5.18.2 Features

- Supports nine DMA channels. Each channel can support a unidirectional transfer
- AMBA AHB master/slave interface compatible, for data transfer and register read/write
- Supports source and destination address increased mode or fixed mode
- Hardware channel priority DMA channel 0 has the highest priority and channel 8 has the lowest priority

### NuMicro™ NUC130/NUC140 Technical Reference Manual

# nuvoTon

### 5.18.3 Block Diagram

Figure 5-110 PDMA Controller Block Diagram

### ηυνοτοη

#### 5.18.4 Functional Description

The PDMA controller has nine channels of DMA associated with Peripheral-to-Memory to-Peripheral or Memory-to-Memory. For each PDMA channel, there is one word memory as transfer buffer between the Peripherals APB IP and Memory.

The CPU can recognize the completion of a PDMA operation by software polling or when it receives an internal PDMA interrupt. As to the source and destination address, the PDMA controller has two modes: increased and fixed.

Every PDMA default channel behavior is not pre-defined, so users must configure the channel service settings of PDMA_PDSSR0, PDMA_PDSSR1 and PDMA_PDSSR2 before start the related PDMA channel.

Software must enable DMA channel PDMA [PDMACEN] and then write a valid source address to the PDMA_SARx register, a destination address to the PDMA_DARx register, and a transfer count to the PDMA_BCRx register. Next, trigger the DMA_CSRx PDMA [TRIG_EN]. PDMA will continue the transfer until PDMA_CBCRx comes down to zero, If an error occurs during the PDMA operation, the channel stops unless software clears the error condition and sets the PDMA_CSRx [SW_RST] to reset the PDMA channel and set PDMA_CSRx [PDMACEN] and [TRIG_EN] bits field to start again.

In PDMA (Peripheral-to-Memory or Memory-to-Peripheral) mode, DMA can transfer data between the Peripherals APB IP (ex: UART, SPI, ADC....) and Memory.

		Block Transfer Done Interrupt Flag					
		This bit indicates that PDMA has finished all transfer.					
[1]	BLKD_IF	1 = Done					
		0 = Not finished yet					
		Software can write 1 to clear this bit to 0					
		PDMA Read/Write Target Abort Interrupt Flag					
[0]	TABORT IF	1 = Bus ERROR response received					
[0]		0 = No bus ERROR response received					
		Software can write 1 to clear this bit to 0					

Note: The PDMA_ISR [TABORT_IF] indicate bus master received ERROR response or not. If bus master received ERROR response, it means that target abort is happened. PDMAC will stop transfer and respond this event to software then go to IDLE state. When target abort occurred, software must reset PDMA, and then transfer those data again.

### 5.19 External Bus Interface (EBI)

#### 5.19.1 Overview

The NuMicro[™] NUC130/NUC140 LQFP-64 and LQFP-100 package h an external bus interface (EBI) for external device used.

To save the connections between external device and this chip, EBI support address bus and data bus multiplex mode. Also, address latch enable (ALE) signal supported differentiate the address and data cycle.

### 5.19.2 Features

External Bus Interface has the following functions:

- External devices with max. 64 Kbytes (8-bit data width)/128 Kbytes (16-bit data width) supported
- Variable external bus base clock (MCLK) supported
- 8-bit or 16-bit data width supported
- Variable data access time (tACC), address latch enable time (tALE) and address hold time (tAHD) supported
- Address bus and data bus multiplex mode supported to save the address pins
- Configurable idle cycle supported for different access condition: Write command finish (W2X), Read-to-Read (R2R)

### 5.19.3 Block Diagram

Figure 5-111 EBI Block Diagram

### 5.19.4 Functional Description

### 5.19.4.1 EBI Area and Address Hit

EBI mapping address is located at 0x6000_0000 ~ 0x6001_FFFF and the total memory space is 128Kbyte. When system request address hit EBI's memory space, the corresponding EBI chip select signal is assert and EBI state machine operates.

For an 8-bit device (64Kbyte), EBI mapped this 64Kbyte device to 0x6000_0000 ~ 0x6000_FFFF and 0x6001_0000 ~ 0x6001_FFFF simultaneously.

### 5.19.4.2 EBI Data Width Connection

EBI support device whose address bus and data bus are multiplexed. For the external device with separated address and data bus, the connection to device needs additional logic to latch the address. In this case, pin ALE is connected to the latch device to latch the address value. Pin AD is the input of the latch device, and the output of the latch device is connected to the address of external device. For 16-bit device, the AD [15:0] shared by address and 16-bit data. For 8-bit device, only AD [7:0] shared by address and 8-bit data, AD [15:8] is dedicated for address and could be connected to 8-bit device directly.

For 8-bit data width, chip system address bit [15:0] is used as the device's address [15:0]. For 16-

bit data width, chip system address bit [16:1] is used as the device's address [15:0] and chip system address bit [0] is useless.

EBI bit width	System address (AHBADR)	EBI address (AD)
8-bit	AHBADR[15:0]	AD[15:0]
16-bit	AHBADR[16:1]	AD[15:0]

Figure 5-112 Connection of 16-bit EBI Data Width with 16-bit Device

Figure 5-113 Connection of 8-bit EBI Data Width with 8-bit Device

When system access data width is lager than EBI data width, EBI controller will finish a system access command by operating EBI access more than once. For example, if system requests a 32-bit data through EBI device, EBI controller will operate accessing four times when setting EBI data width with 8-bit.

## ηυνοτοη

#### 5.19.4.3 EBI Operating Control

#### MCLK Control

In the chip, all EBI signals will be synchronized by MCLK when EBI is operating. When chip connects to the external device with slower operating frequency, the MCLK can divide most to HCLK/32 by setting MCLKDIV of register EBICON. Therefore, chip can suitable for a wide frequency range of EBI device. If MCLK is set to HCLK/1, EBI signals are synchronized by positive edge of MCLK, else by negative edge of MCLK.

#### **Operation and Access Timing Control**

In the start of access, chip select (nCS) asserts to low and wait one MCLK for address setup time (tASU) for address stable. Then ALE asserts to high after address is stable and keeps for a period of time (tALE) for address latch. After latch address, ALE asserts to low and wait one MCLK for latch hold time (tLHD) and another one MCLK cycle (tA2D) that is inserted behind address hold time to be the bus turn-around time for address change to data. Then nRD asserts to low when read access or nWR asserts to low when write access. Then nRD or nWR asserts to high after keeps access time (tACC) for reading output stable or writing finish. After that, EBI signals keep for data access hold time (tAHD) and chip select asserts to high, address is released by current access control.

EBI controller provides a flexible timing control for different external device. In EBI timing control, tASU, tLHD and tA2D are fixed to 1 MCLK cycle, tAHD can modulate to 1~8 MCLK cycles by setting ExttAHD of register EXTIME, tACC can modulate to 1~32 MCLK cycles by setting ExttACC of register EXTIME, and tALE can modulate to 1~8 MCLK cycles by setting tALE of register EBICON.

Parameter	Value	Unit	Description
tASU	1	MCLK	Address Latch Setup Time.
tALE	1 ~ 8	MCLK	ALE High Period. Controlled by ExttALE of EBICON.
tLHD	1	MCLK	Address Latch Hold Time.
tA2D	1	MCLK	Address To Data Delay (Bus Turn-Around Time).
tACC	1 ~ 32	MCLK	Data Access Time. Controlled by ExttACC of EXTIME.
tAHD	1 ~ 8	MCLK	Data Access Hold Time. Controlled by ExttAHD of EXTIME.
IDLE	0 ~ 15	MCLK	Idle Cycle. Controlled by ExtIR2R and ExtIW2X of EXTIME.

# nuvoTon

Figure 5-114 Timing Control Waveform for 16-bit Data Width

Figure 5-114 is an example of setting 16-bit data width. In this example, AD bus is used for being address[15:0] and data[15:0]. When ALE assert to high, AD is address output. After address is latched, ALE asserts to low and the AD bus change to high impedance to wait device output data in read access operation, or it is used for being write data output.

## nuvoTon

Figure 5-115 Timing Control Waveform for 8-bit Data Width

Figure 5-115 is an example of setting 8-bit data width. The difference between 8-bit and 16-bit data width is AD[15:8]. In 8-bit data width setting, AD[15:8] always be Address[15:8] output so that external latch need only 8-bit width.

# nuvoTon

#### **Insert Idle Cycle**

When EBI accessing continuously, there may occur bus conflict if the device access time is much slow with system operating. EBI controller supply additional idle cycle to solve this problem. During idle cycle, all control signals of EBI are inactive. Figure 5-116 show idle cycle as below:

Figure 5-116 Timing Control Waveform for Insert Idle Cycle

There are two conditions that EBI can insert idle cycle by timing control:

- 1. After write access
- 2. After read access and before next read access

By setting ExtIW2X, and ExtIR2R of register EXTIME, the time of idle cycle can be specified from 0~15 MCLK.

### 6 FLASH MEMORY CONTROLLER (FMC)

### 6.1 Overview

The NuMicro[™] NUC100 Series is equipped with 128/64/32K bytes on-chip embedded Flash for application program memory (APROM) that can be updated through ISP procedure. In System Programming (ISP) function enables user to update program memory when chip is soldered on PCB. After chip power on, Cortex-M0 CPU fetches code from APROM or LDROM decided by boot select (CBS) in Config0. Also, the NuMicro[™] NUC100 Series also provides additional DATA Flash for user, to store some application dependent data before chip power off. For 128K bytes APROM device, the data flash is shared with original 128K program memory and its start address is configurable and defined by user application request in Config1. For 64K/32K bytes APROM device, the data flash is fixed at 4K.

### 6.2 Features

- Runs up to 50 MHz with zero wait state for continuous address read access
- 128/64/32KB application program memory (APROM)
- 4 KB In System Programming (ISP) loader program memory (LDROM)
- Configurable or fixed 4 KB data flash with 512 bytes page erase unit
- Programmable data flash start address for 128K APROM device
- In System Program (ISP) to update on chip Flash

### 6.3 Block Diagram

The flash memory controller consists of AHB slave interface, ISP control logic, writer interface and flash macro interface timing control logic. The block diagram of flash memory controller is shown as follows:

Figure 6-1 Flash Memory Control Block Diagram

### 6.4 Flash Memory Organization

The NuMicro[™] NUC100 Series flash memory consists of Program memory (128/64/32KB), data flash, ISP loader program memory, user configuration. User configuration block provides several bytes to control system logic, such as flash security lock, boot select, Brown-out voltage level, data flash base address, etc. It works like a fuse for power on setting. It is loaded from flash memory to its corresponding control registers during chip power on. User can set these bits according to application request by writer before chip is mounted on PCB. The data flash start address and its size can defined by user depends on application in 128KB APROM device. For 64/32KB APROM devices, its size is 4KB and start address is fixed at 0x0001_F000.

Block Name	Size	Start Address	End Address	
AP-ROM	32/64/(128-0.5*N) KB	0x0000_0000	0x0000_7FFF (32KB) 0x0000_FFFF (64KB) DFBADR-1 (128KB if DFEN=0)	
Reserved for future use	Reserved for future use 896KB		0x000F_FFFF	
Data Flash 4/4/0.5*N KB		0x0001_F000 DFBADR	0x0001_FFFF	
LD-ROM	4 KB	0x0010_0000	0x0010_0FFF	
User Configuration 2 words		0x0030_0000	0x0030_0004	

Table 6-1 Memory Address Map

### 6.5 Boot Selection

The NuMicro[™] NUC100 Series provides the In System Programming (ISP) feature to enable user to update program memory when chip is mounted on PCB. A dedicated 4KB program memory is used to store ISP firmware. Users can select to start program fetch from APROM or LDROM by (CBS) in Config0.

### 6.6 Data Flash

The NuMicro[™] NUC100 Series provides data flash for user to store data. It is read/write through ISP procedure. The size of each erase unit is 512 bytes. When a word will be changed, all 128 words need to be copied to another page or SRAM in advance. For 128KB APROM device, the data flash and application program share the same 128KB memory, if DFEN bit in Config0 is enabled, the data flash base address is defined by DFBADR and application program memory size is (128-0.5*N)KB and data flash size is 0.5*N KB. For 64/32KB APROM devices, data flash size is 4KB and start address is fixed at 0x0001_F000.

	Description				
	Reserved	Reserved (It is mandatory to program 0x00 to these Reserved bits)			
[19:0]	DFBADR	Data Flash Base Address (Only for 128KB APROM Device) For 128KB APROM device, its data flash base address is defined by user. Since on chip flash erase unit is 512 bytes, it is mandatory to keep bit 8-0 as 0. This configuration is only valid for 128KB flash device.			

### 6.8 In System Program (ISP)

The program memory and data flash supports both in hardware programming and in system programming (ISP). Hardware programming mode uses gang-writers to reduce programming costs and time to market while the products enter the mass production state. However, if the product is just under development or the end product needs firmware updating in the hand of an end user, the hardware programming mode will make repeated programming difficult and inconvenient. ISP method makes it easy and possible. The NuMicro™ NUC100 Series supports ISP mode allowing a device to be reprogrammed under software control. Furthermore, the capability to update the application firmware makes wide range of applications possible.

ISP is performed without removing the microcontroller from the system. Various interfaces enable LDROM firmware to get new program code easily. The most common method to perform ISP is via UART along with the firmware in LDROM. General speaking, PC transfers the new APROM code through serial port. Then LDROM firmware receives it and re-programs into APROM through ISP commands. Nuvoton provides ISP firmware and PC application program for NuMicro[™] NUC100 Series. It makes users quite easy perform ISP through Nuvoton ISP tool.

### 6.8.1 ISP Procedure

The NuMicro[™] NUC100 Series supports booting from APROM or LDROM initially defined by user configuration bit (CBS). If user wants to update application program in APROM, he can write BS=1 and starts software reset to make chip boot from LDROM. The first step to start ISP function is write ISPEN bit to 1. S/W is required to write REGWRPROT register in Global Control Register (GCR, 0x5000_0100) with 0x59, 0x16 and 0x88 before writing ISPCON register. This procedure is used to protect flash memory from destroying owning to unintended write during power on/off duration.

Several error conditions are checked after software writes ISPGO bit. If error condition occurs, ISP operation is not been started and ISP fail flag will be set instead of. ISPFF flag is cleared by s/w, it will not be over written in next ISP operation. The next ISP procedure can be started even ISPFF bit keeps at 1. It is recommended that s/w to check ISPFF bit and clear it after each ISP operation if it is set to 1.

When ISPGO bit is set, CPU will wait for ISP operation finish, during this period, peripheral still keeps working as usual. If any interrupt request occur, CPU will not service it till ISP operation finish. When ISP operation is finished, the ISPGO bit will be cleared by hardware automatically. User can know if ISP operation is finished by checking this bit. User should add ISB instruction next to the instruction which set 1 to ISPGO bit to ensure correct execution of the instructions following ISP operation.

#### Note:

1. /RESET pin is a Schmitt trigger input.

2. Crystal Input is a CMOS input.

3. Pins PA, PB, PC, PD and PE can source a transition current when they are being externally driven from 1 to 0. In the

condition of V_{DD}=5.5 V, 5he transition current reaches its maximum value when V_{IN} approximates to 2 V.

#### 9 REVISION HISTORY

REVISION	DATE	DESCRIPTION			
V2.00	May 04, 2011	1. Originated from the NUC100 series TRM			
v2.00 Iviay 04, 201		2. Updated CAN peripheral to BOSCH C-CAN			
		1. Revised the ISPCON.BS and ISPCON.ISPFF description			
		2. Modified the temperature sensor spec			
V2.01	June 14, 2011	3. Revised the pin description for multi-function T2EX, T3EX, nRD, nWR			
		4. Updated the title of SPI Dynamic Characteristics			
		5. Updated BOD spec			
		1. Updated the WDT block diagram			
		2. Released PDMA/debug register in UA_ISR register			
		3. Removed the feature "Dynamic priority changing" for NVIC			
		4. Modified the INIR description in RTC register			
		5. Modified the description for RTC compensation			
		6. Revised the R/W description for TDR and TCAP			
V2.02	Jan. 2, 2012	7. Revised the TWKE description			
		8. Revised the AER description			
		9. Revised AER effect from 512 clock to 1024 clock			
		10. Modified the ADC analog characteristic spec			
		11. Modified the description of PWM sample procedure			
		12. Removed the TX_FULL and RX_FULL description, and revised the TX_POINTER and RX_POINTER description			
		13. Removed SPI FIFO mode			
V2.04	May 04, 2012	1. Updated all format and description			
		1. Updated the PDID table			
V2.05	Aug 22, 2013	3 2. Updated UART_CLK / (A+2), A must >=7			
324		3. Remove ET and PT register			

#### **Important Notice**

Nuvoton Products are neither intended nor warranted for usage in systems or equipment, any malfunction or failure of which may cause loss of human life, bodily injury or severe property damage. Such applications are deemed, "Insecure Usage".

Insecure usage includes, but is not limited to: equipment for surgical implementation, atomic energy control instruments, airplane or spaceship instruments, the control or operation of dynamic, brake or safety systems designed for vehicular use, traffic signal instruments, all types of safety devices, and other applications intended to support or sustain life.

All Insecure Usage shall be made at customer's risk, and in the event that third parties lay claims to Nuvoton as a result of customer's Insecure Usage, customer shall indemnify the damages and liabilities thus incurred by Nuvoton.

Please note that all data and specifications are subject to change without notice. All the trademarks of products and companies mentioned in this datasheet belong to their respective owners.
