

DDR 13-Bit to 26-Bit Registered Buffer

ICSSSTV16859C
Recommended Applications:

- DDR Memory Modules
- Provides complete DDR DIMM logic solution with ICS93V857 or ICS95V857
- SSTL_2 compatible data registers

Product Features:

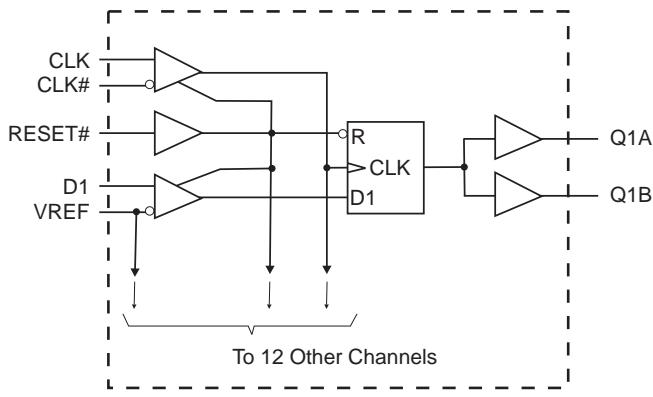

- Differential clock signals
- Meets SSTL_2 signal data
- Supports SSTL_2 class II specifications on outputs
- Low-voltage operation
- $V_{DD} = 2.3V$ to $2.7V$
- Available in 64 pin TSSOP and 56 pin VFQFN (MLF2) packages

Truth Table¹

RESET#	CLK	CLK#	D	Q
L	X or Floating	X or Floating	X or Floating	L
H	↑	↓	H	H
H	↑	↓	L	L
H	L or H	L or H	X	$Q_0^{(2)}$

Notes:

1. H = "High" Signal Level
L = "Low" Signal Level
↑ = Transition "Low"-to-"High"
↓ = Transition "High"-to-"Low"
X = Don't Care
2. Output level before the indicated steady state input conditions were established.

General Description

The 13-bit-to-26-bit ICSSSTV16859C is a universal bus driver designed for 2.3V to 2.7V V_{DD} operation and SSTL_2 I/O levels, except for the LVCMS RESET# input.

Data flow from D to Q is controlled by the differential clock (CLK/CLK#) and a control signal (RESET#). The positive edge of CLK is used to trigger the data flow and CLK# is used to maintain sufficient noise margins where as RESET#, an LVCMS asynchronous signal, is intended for use at the time of power-up only. ICSSSTV16859C supports low-power standby operation. A logic level "Low" at RESET# assures that all internal registers and outputs (Q) are reset to the logic "Low" state, and all input receivers, data (D) and clock (CLK/CLK#) are switched off. Please note that RESET# must always be supported with LVCMS levels at a valid logic state because VREF may not be stable during power-up.

To ensure that outputs are at a defined logic state before a stable clock has been supplied, RESET# must be held at a logic "Low" level during power up.

In the DDR DIMM application, RESET# is specified to be completely asynchronous with respect to CLK and CLK#. Therefore, no timing relationship can be guaranteed between the two signals. When entering a low-power standby state, the register will be cleared and the outputs will be driven to a logic "Low" level quickly relative to the time to disable the differential input receivers. This ensures there are no glitches on the output. However, when coming out of low-power standby state, the register will become active quickly relative to the time to enable the differential input receivers. When the data inputs are at a logic level "Low" and the clock is stable during the "Low"-to-"High" transition of RESET# until the input receivers are fully enabled, the design ensures that the outputs will remain at a logic "Low" level.

Notes:

1. The input and output negative voltage ratings may be excluded if the input and output clamp ratings are observed.
2. This current will flow only when the output is in the high state level $V_0 > V_{DDQ}$.
3. The package thermal impedance is calculated in accordance with JESD 51.

Stresses above those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These ratings are stress specifications only and functional operation of the device at these or any other conditions above those listed in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect product reliability.

- Notes:
- CL includes probe and jig capacitance.
 - I_{DD} tested with clock and data inputs held at V_{DDQ} or GND, and I_O = 0 mA.
 - All input pulses are supplied by generators having the following characteristics: PRR @10 MHz, Z_o=50Ω, input slew rate = 1 V/ns ±20% (unless otherwise specified).
 - The outputs are measured one at a time with one transition per measurement.
 - V_{TT} = V_{REF} = V_{DDQ}/2
 - V_{IH} = V_{REF} + 310mV (AC voltage levels) for differential inputs. V_{IH} = V_{DDQ} for LVC MOS input.
 - V_{IL} = V_{REF} - 310mV (AC voltage levels) for differential inputs. V_{IL} = GND for LVC MOS input.
 - t_{PLH} and t_{PHL} are the same as t_{pd}
